Metric Learning for MIR

Part 1 - Foundations

Brian McFee Jongpil Lee Juhan Nam

NYU Center for Data Science

MARL

KAIST

Tutorial outline

- **Part 1: Foundations (Brian McFee)**
  - Linear metric learning methods
  - Overview of applications in MIR
  - Coding practice

- Part 2: Deep metric learning (Jongpil Lee)
  - Linear metric learning to deep metric learning
  - Advanced models
  - Coding practice

- Part 3: Variations and modern applications (Juhan Nam)
  - Cross-modality metric learning
  - Unsupervised learning

- Closing remarks

Similarity is everywhere inMIR!

- **Search** and **recommender systems** rely on similarity between songs, artists, albums, lyrics, tags, etc.
- **Cover song identification** uses similarity to determine if two recordings are of the same composition
- **Structural segmentation** uses similarity or dissimilarity between features to infer repetition, parallelism, and novelty
- **Nearest neighbor classifiers** use similarity to propagate information (eg, tags) from labeled to unlabeled data

Similarity is everywhere inMIR!

- **Search** and **recommender systems** rely on similarity between songs, artists, albums, etc.
- **Cover song** identification: measure similarity to determine if two songs are of the same comp
- **Structural** s res to infer repetition, parallelism, and novelty
- **Nearest neighbor classifiers** use similarity to propagate information (eg, tags) from labeled to unlabeled data

But what is “similarity”?

Similarity and metric learning

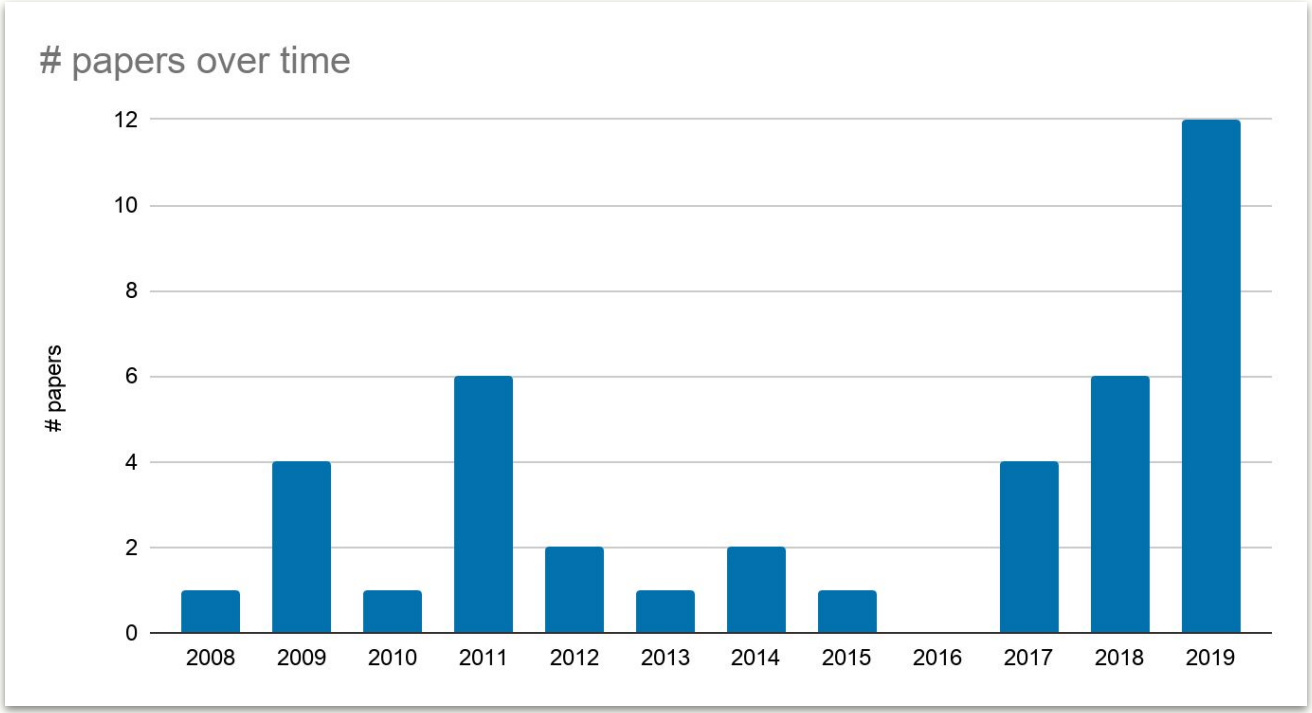
- For some applications, you can design an algorithm to compute similarity. But is it ***good***? Is it ***optimal***?
- **Metric learning** is the problem of learning how to compare items.
- We'll need some supervision (examples) to tell us what similarity should be. (a.k.a. Training data)
- From this, we'll learn a function to compare two items through a **distance metric**

Some reasons to use metric learning

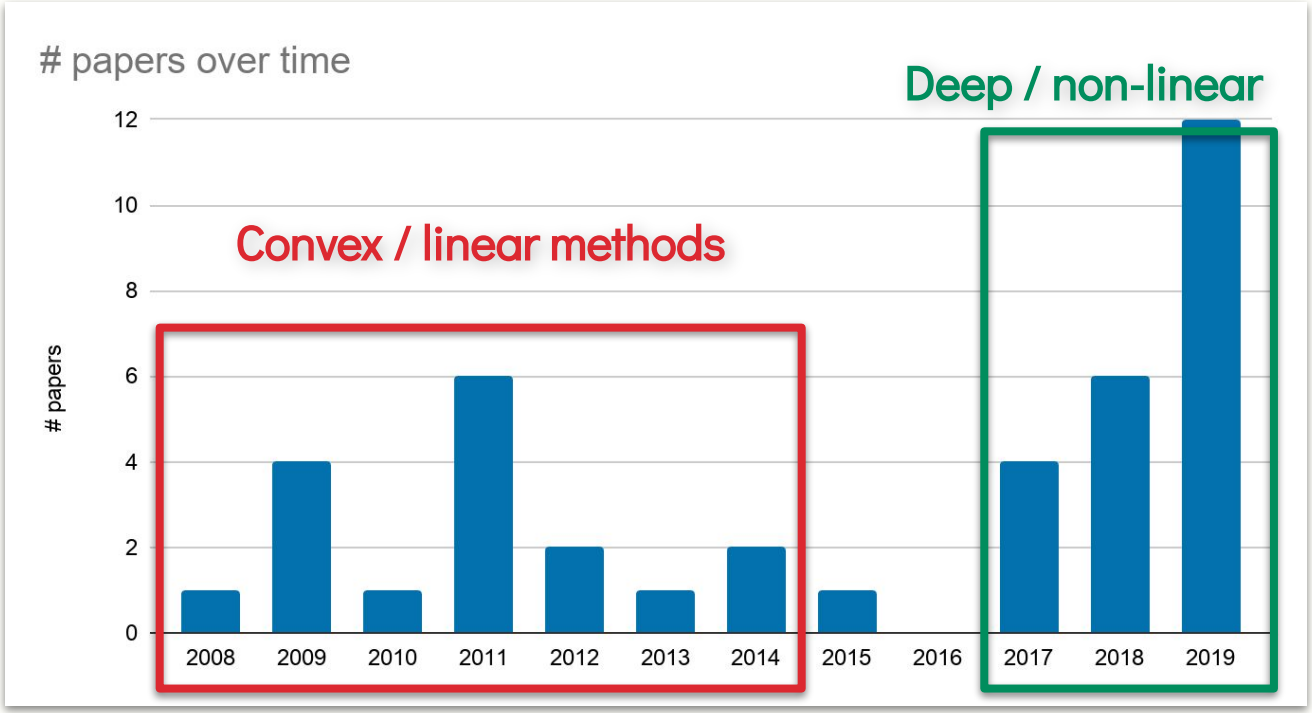
- Large or unbounded class vocabularies
  - Nearest neighbor methods will naturally support this
  - **Metric learning improves nearest neighbors!**
  - Example: cover detection

- Non-dichotomous notion of similarity
  - **Metric learning can be trained for rank-ordering data, not just same/different!**
  - Example: recommendation and similarity judgments

- Your classification problem naturally involves pairs of items
  - **Distance between vector representations is a flexible model**
  - Example: structure analysis



Timeline of metric learning in MIR (ISMIR, ICASSP, & related venues)



Timeline of metric learning in MIR (ISMIR, ICASSP, & related venues)

Distance metrics

- Let $x_1, x_2 \in \mathbb{R}^D$ denote two data points to be compared
- The (squared) Euclidean distance is

$$\|x_1 - x_2\|^2 = (x_1 - x_2)^\top (x_1 - x_2) = \sum_d (x_1[d] - x_2[d])^2$$

Distance metrics

- Let $x_1, x_2 \in \mathbb{R}^D$ denote two data points to be compared
- The (squared) Euclidean distance is

$$\|x_1 - x_2\|^2 = (x_1 - x_2)^\top (x_1 - x_2) = \sum_d (x_1[d] - x_2[d])^2$$

- **Linear metric learning** seeks a projection $M \in \mathbb{R}^{D \times D}$:

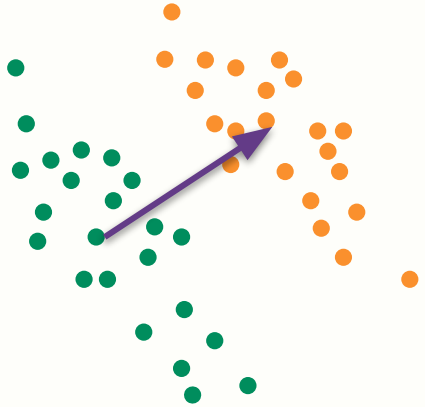
$$\|Mx_1 - Mx_2\|^2 = (Mx_1 - Mx_2)^\top (Mx_1 - Mx_2) = (x_1 - x_2)^\top M^\top M (x_1 - x_2)$$

- After projection, **similar** points should have **small distance** and **dissimilar** points should have **large distance**

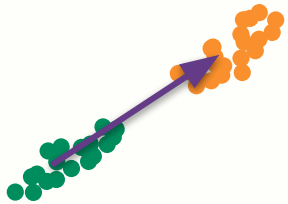
Linear discriminant analysis

[Fisher; 1935]

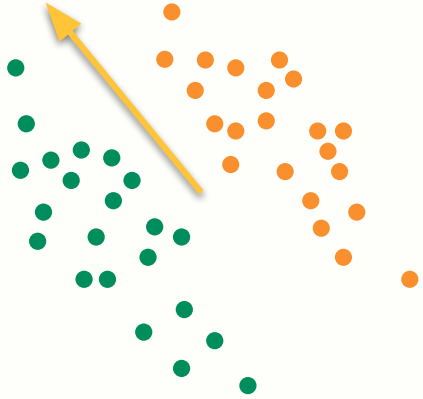
- Assume we have data in two classes: $Y = \{0, 1\}$



- **Minimize** distance between points from the **same class**
- **Maximize** distance between points of **different classes**
- If two classes are **linearly separable**, then **one direction** is enough.
  Using more dimensions would only increase distances.



LDA

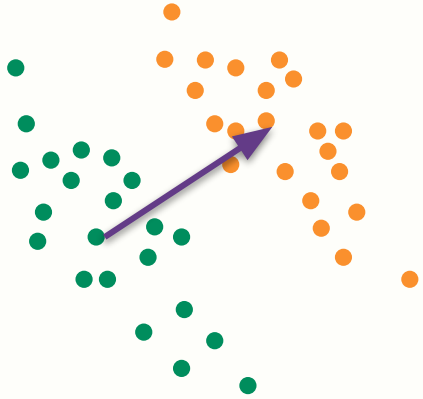


- "Average (squared) distance" is **variance!**
- Find a direction that simultaneously minimizes **within-class** variance and maximizes **between-class** variance

- Principal components analysis (PCA): direction(s) to **maximize total variance**
  ⇒ leading eigenvector(s) of the covariance matrix Σ

$$\max_{m} m^{\top}\Sigma m \quad \text{such that} \quad \|m\| = 1$$

LDA



- "Average (squared) distance" is **variance!**
- Find a direction that simultaneously minimizes **within-class** variance and maximizes **between-class** variance
- $\min_m m^T(\Sigma_0 + \Sigma_1)m \;/\; m^T(\Sigma_{01})m$
  s.t. $\|m\| = 1$
- This can be solved efficiently by "generalized Eigenvectors": $(\Sigma_0 + \Sigma_1)m = \lambda\Sigma_{01}m$

Relaxing the assumptions

- LDA makes **strong assumptions** about the data
  - Gaussianity + Linear separability
- **Metric learning** is well suited to **nearest neighbor** methods, which don't need those assumptions!
- Starting with [Xing et al., 2002], there are now many algorithms to learn distance metrics in various settings
- Algorithms differ mainly in what form of **supervision** is required, and how exactly distances are compared / optimized

Different kinds of supervision

- Class labels:

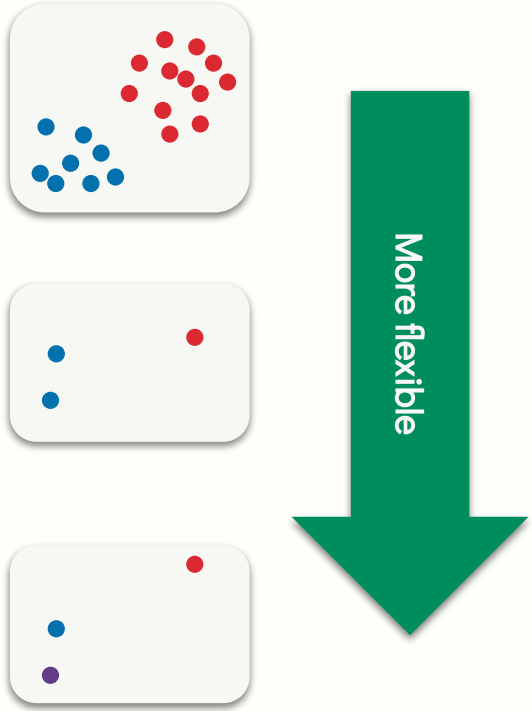
  (x, y)

- Pairwise **similarity**/**dissimilarity**:

  $(x_1, x_2, \pm)$

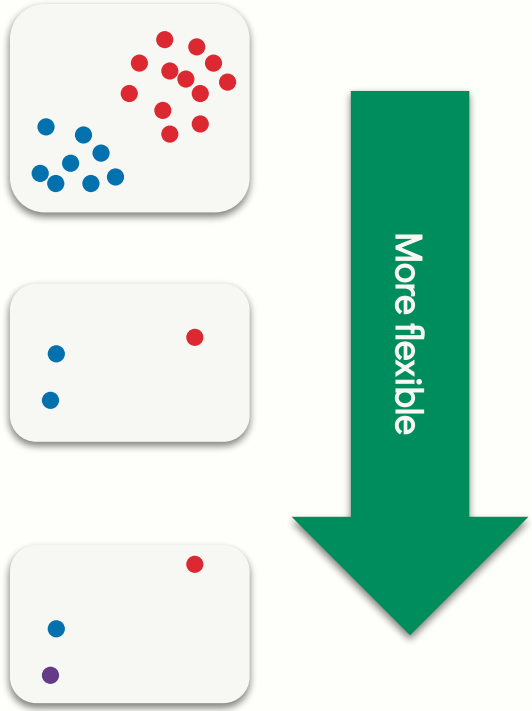
- **Relative** comparisons (**triplets**):

  $(x_1, x_2, x_3) \quad \Rightarrow \quad d(x_1, x_2) < d(x_1, x_3)$



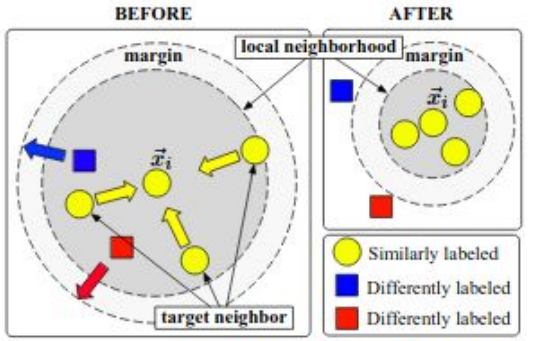
What supervision is right for you?

- Is it reasonable for **all examples of a class** to cluster together?
- Or are locally consistent neighborhoods good enough? Can you identify good pairs?
- Do you even have class labels, or some other source of similarity judgments?



Large Margin Nearest Neighbors*

[Weinberger, Blitzer, Saul; 2006]



- For each example x_i, find k nearest "target" neighbors $\{x_j\}$ with the **same label** as x_i

- Each of these targets should be closer to x_i than any other **differently labeled point x_k by at least a margin**

$$\min_M \sum_{(i,j,k)} \max(0,\ \|Mx_i - Mx_j\|^2 - \|Mx_i - Mx_k\|^2 + 1)$$

- Optimize M by (stochastic) gradient descent on training data

*simplified for presentation

Coding time!

Summary of part 1

- We've seen how to learn a **linear transformation** of feature vectors that improves nearest neighbor classification / retrieval
- By learning the distance metric for a given task, we can be more inclusive of different features and representations.
- In part 2, we'll see how the same basic concepts can be extended to **non-linear transformations** using deep learning!

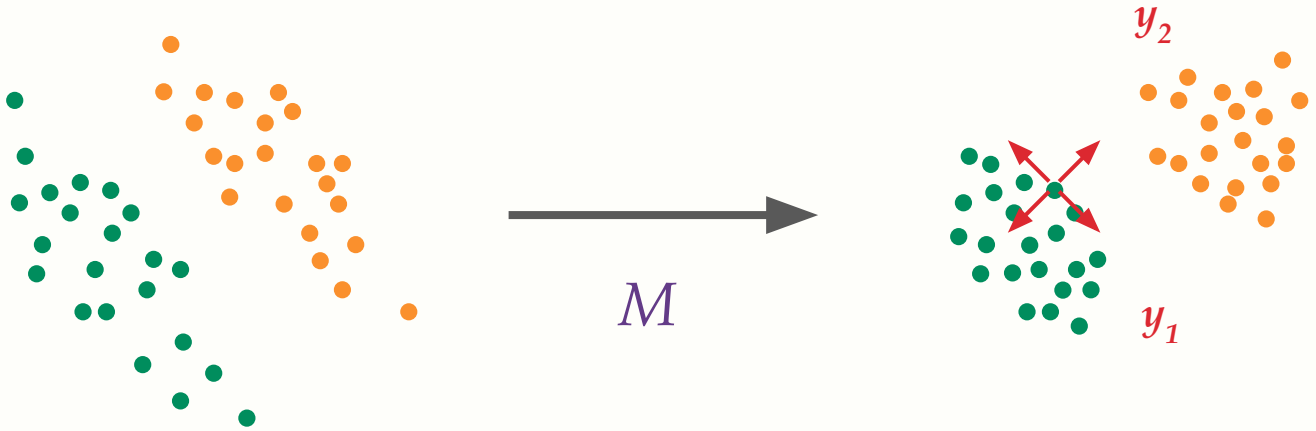
- Closing remarks

Linear metric learning



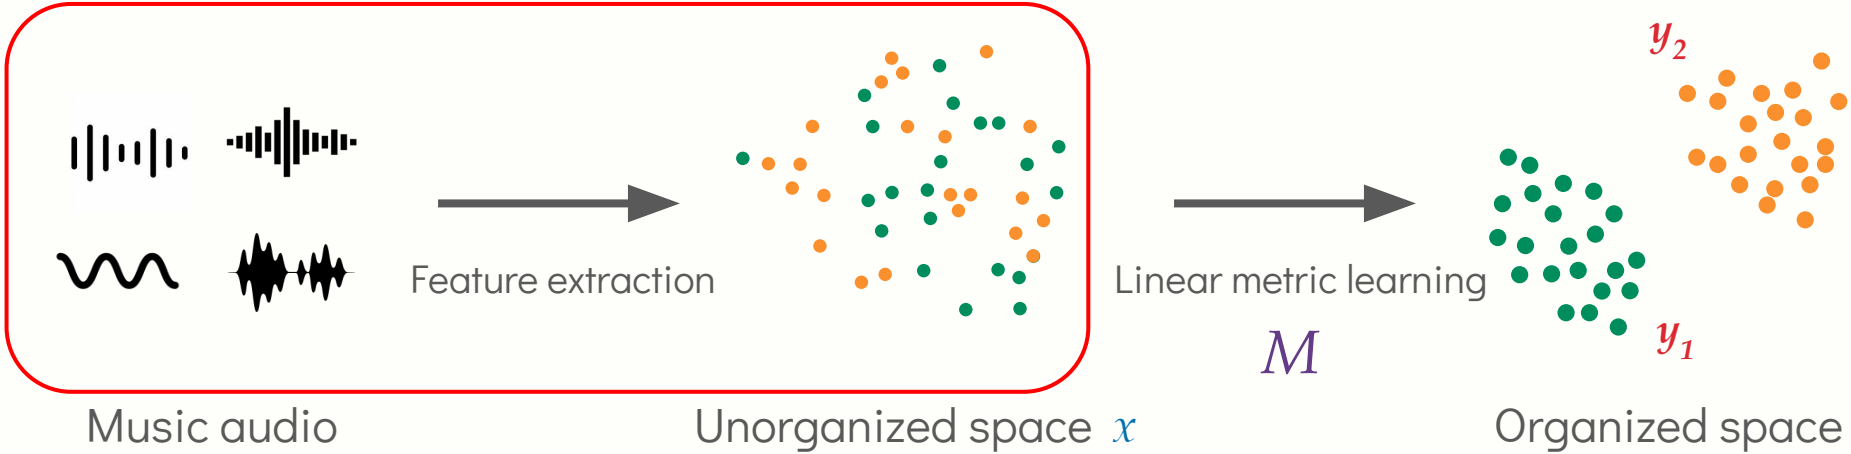
Large Margin Nearest Neighbors (LMNN)

$$(x, y) \text{ or } (x_i, x_j, x_k) \Rightarrow d(x_i, x_j) < d(x_i, x_k)$$

$$\|Mx_1 - Mx_2\|^2 = (Mx_1 - Mx_2)^\top (Mx_1 - Mx_2) = (x_1 - x_2)^\top M^\top M (x_1 - x_2)$$

$$\min_M \sum_{(i,j,k)} \max\left(0, \|Mx_i - Mx_j\|^2 - \|Mx_i - Mx_k\|^2 + 1\right)$$

Linear metric learning to deep metric learning

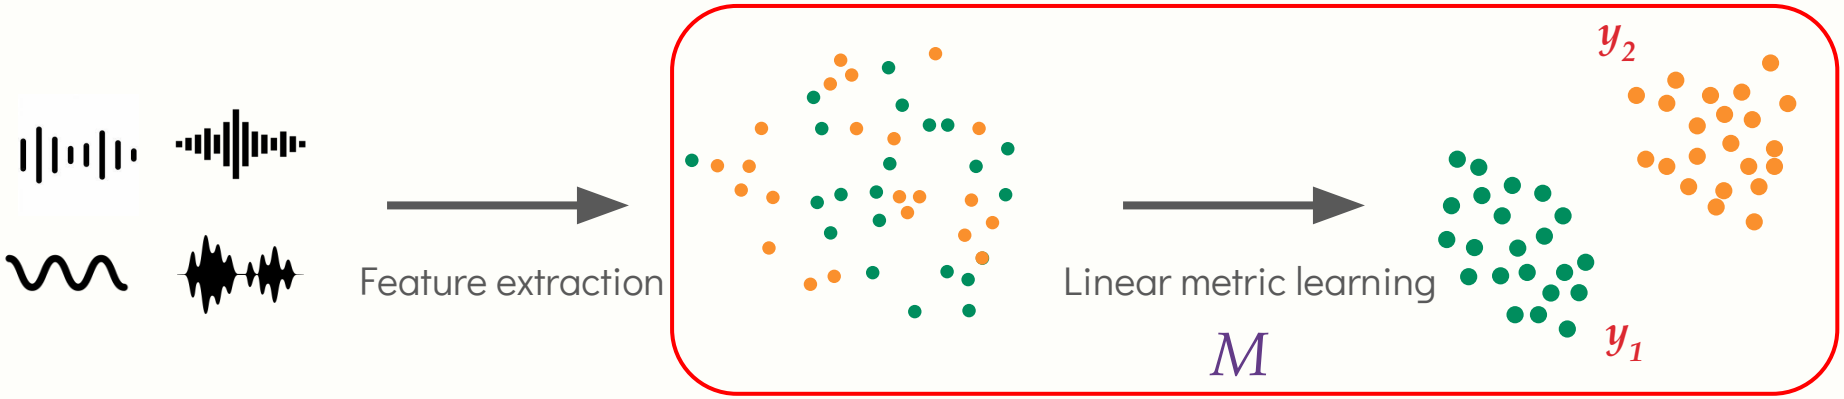


$$(x, y) \text{ or } (x_i, x_j, x_k) \Rightarrow d(x_i, x_j) < d(x_i, x_k)$$

$$\|Mx_1 - Mx_2\|^2 = (Mx_1 - Mx_2)^\top (Mx_1 - Mx_2) = (x_1 - x_2)^\top M^\top M (x_1 - x_2)$$

$$\min_M \sum_{(i,j,k)} \max\left(0, \|Mx_i - Mx_j\|^2 - \|Mx_i - Mx_k\|^2 + 1\right)$$

Linear metric learning to deep metric learning

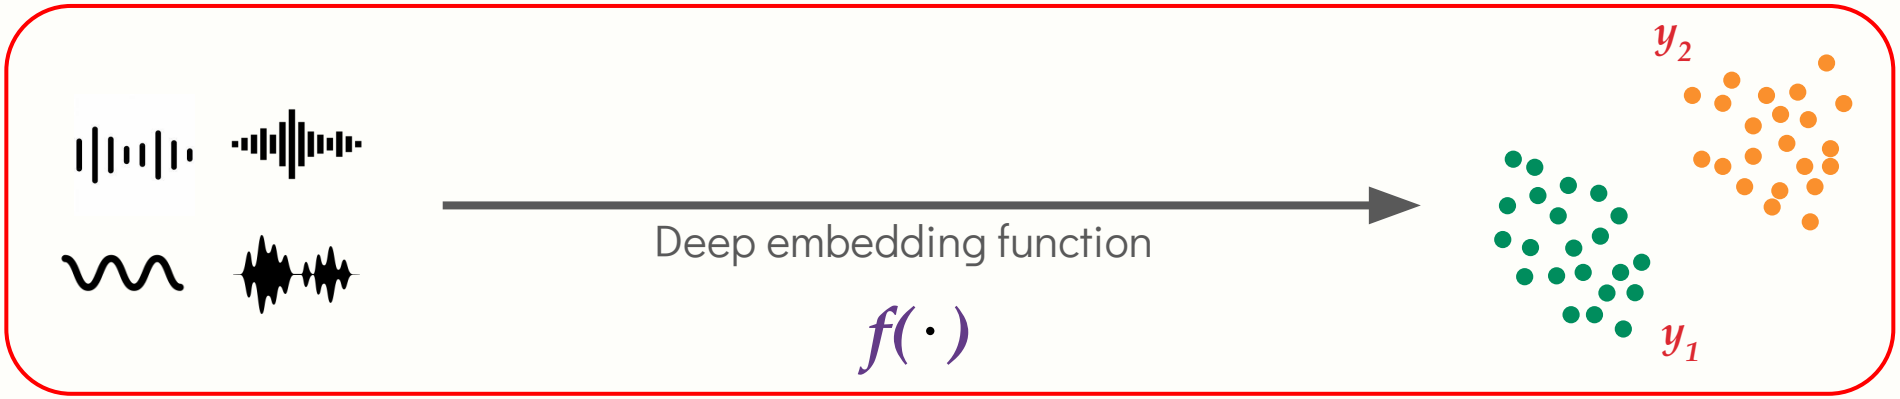


(x, y) or $(x_i, x_j, x_k) \Rightarrow d(x_i, x_j) < d(x_i, x_k)$

$$\|Mx_1 - Mx_2\|^2 = (Mx_1 - Mx_2)^\top (Mx_1 - Mx_2) = (x_1 - x_2)^\top M^\top M (x_1 - x_2)$$

$$\min_M \sum_{(i,j,k)} \max\left(0, \|Mx_i - Mx_j\|^2 - \|Mx_i - Mx_k\|^2 + 1\right)$$

Linear metric learning to deep metric learning



Music audio x

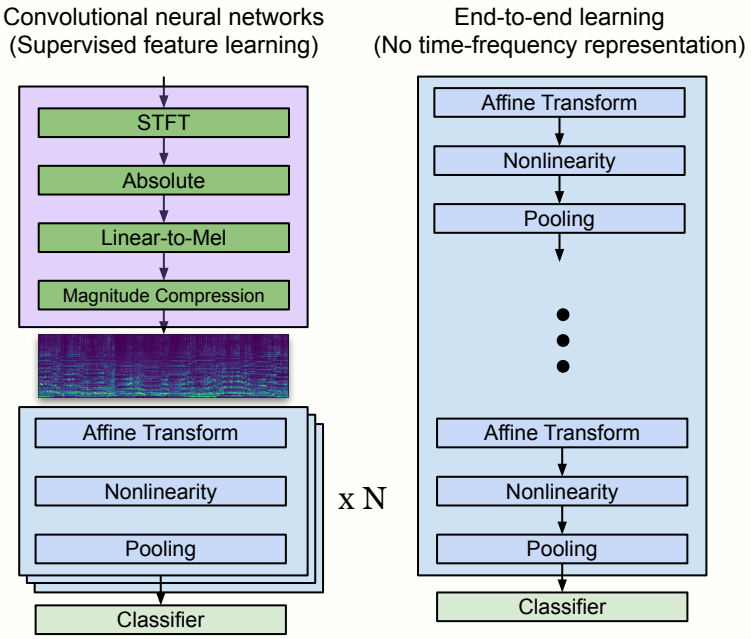
$$(x, y) \text{ or } (x_i, x_j, x_k) \Rightarrow d(x_i, x_j) < d(x_i, x_k)$$

$$D(f(x_1), f(x_2)) = \|f(x_1) - f(x_2)\|^2, \textit{ distance metric or similarity metric}$$

$$\min_f \sum_{(i,j,k)} \max(0, \|f(x_i) - f(x_j)\|^2 - \|f(x_i) - f(x_k)\|^2 + \alpha)$$

Deep embedding function $f(\cdot)$ (backbone model)

[Humphrey et al., 2013, Nam et al., 2018, Pons et al., 2019]

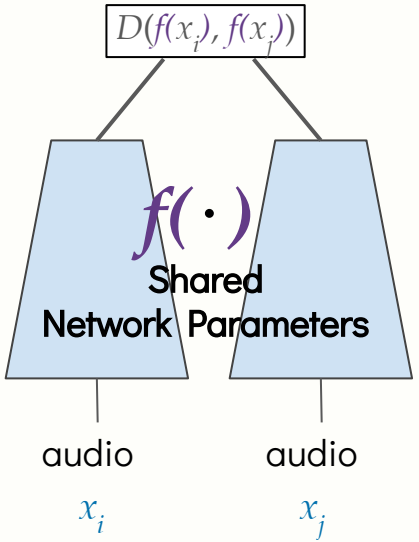


- Any deep nonlinear embedding function
- Gradient descent optimization
- Audio, deep embedding features

Siamese networks

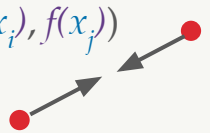
[Hadsell et al., 2006]

$$D(f(x_i), f(x_j)) = \|f(x_i) - f(x_j)\|_2$$

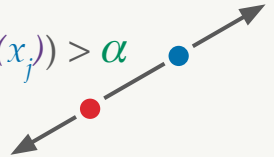


$(x_i, x_j, y) \Rightarrow$

Minimize $D(f(x_i), f(x_j))$, if $y = 1$



$D(f(x_i), f(x_j)) > \alpha$, if $y = 0$

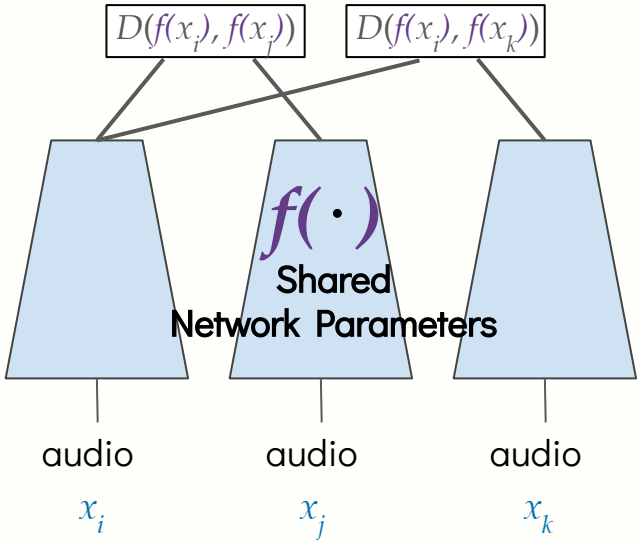


Contrastive loss

$$\min_f \sum_{(i,j,y)} (1 - y)\frac{1}{2} D(f(x_i), f(x_j))^2 + (y)\ \frac{1}{2}\max\left(0, \alpha - D(f(x_i), f(x_j))\right)^2$$

Triplet networks

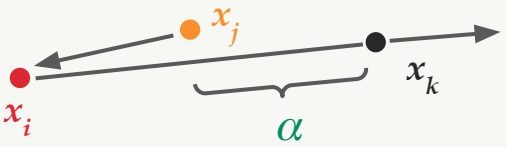
[Hoffer and Ailon, 2015]



$$D(f(x_i), f(x_j)) = \|f(x_i) - f(x_j)\|^2$$

x_i, x_j are the same class, not x_k

$$(x_i, x_j, x_k) \Rightarrow D(f(x_i), f(x_j)) + \alpha < D(f(x_i), f(x_k))$$



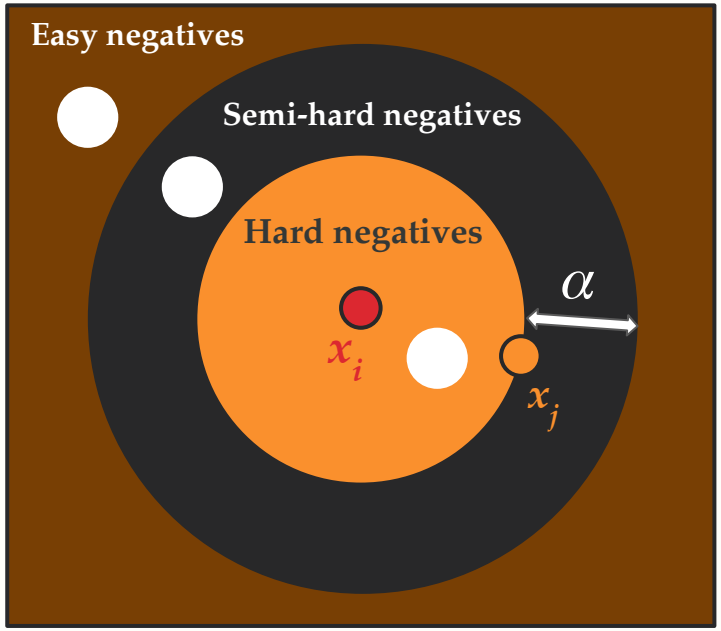
Triplet hinge loss

$$\min_f \sum_{(i,j,k)} \max\left(0,\ D(f(x_i), f(x_j)) - D(f(x_i), f(x_k)) + \alpha\right)$$

Triplet sampling matters

[Wu et al., 2017]

(x_i, x_j, x_k) $\begin{cases} x_i: \text{ anchor sample} \\ x_j: \text{ positive sample} \\ x_k: \text{ negative sample} \end{cases}$



- Easy negatives

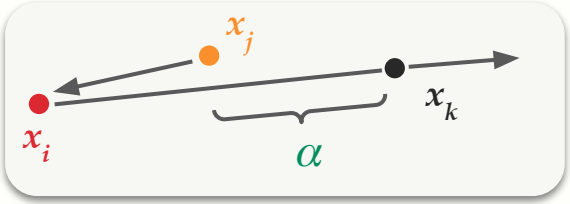
$$D(f(x_i), f(x_j)) + \alpha < D(f(x_i), f(x_k))$$

- Hard negatives

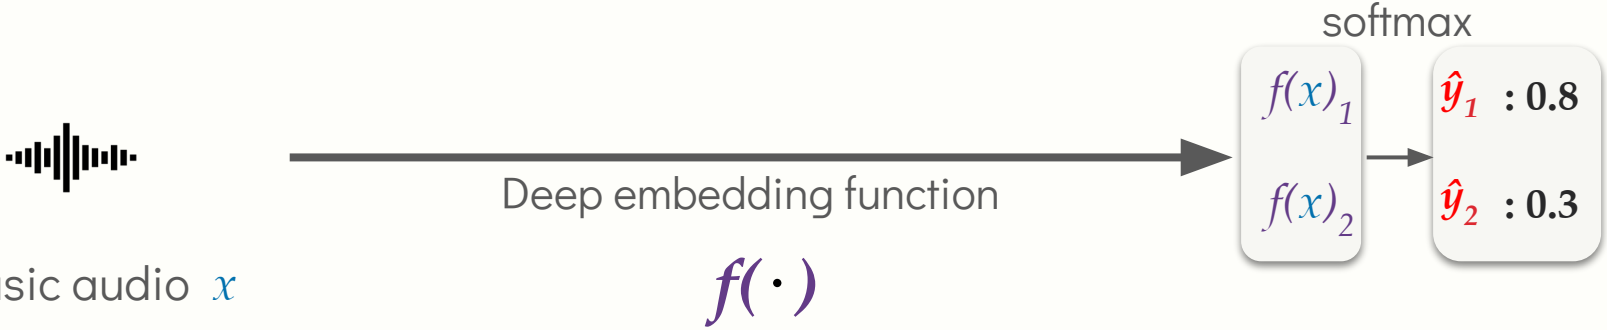
$$D(f(x_i), f(x_j)) > D(f(x_i), f(x_k))$$

- Semi-hard negatives

$$D(f(x_i), f(x_j)) < D(f(x_i), f(x_k)) < D(f(x_i), f(x_j)) + \alpha$$



Classification



$$(x, y)$$

$$\hat{y}_z = \text{softmax}(f(x)_z) = \frac{\exp(f(x)_z)}{\sum_z \exp(f(x)_z)}$$

$$\min_f - \sum_z y_z \log(\hat{y}_z)$$

Classification

Music audio x

Deep embedding function

$f_{n-1}(\cdot)$

Last hidden layer features

$f_{n-1}(x)$

The last hidden layer

$h = [c_1, c_2]$

softmax

$f(x)_1$

$f(x)_2$

$\hat{y}_1$: 0.8

$\hat{y}_2$: 0.3

where c_z is a centroid of class z

$$f(x) = f_{n-1}(x) \square \quad h$$

$$f(x)_z = f_{n-1}(x) \square \quad c_z$$

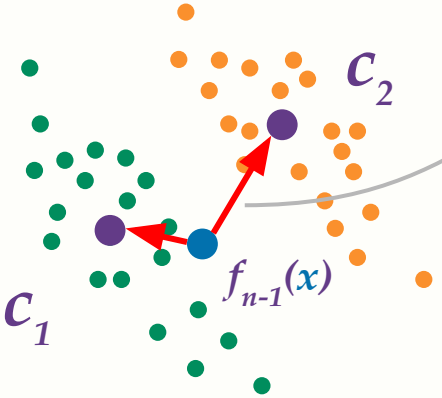
$$\hat{y}_z = \text{softmax}(f_{n-1}(x) \square c_z) = \frac{\exp(f_{n-1}(x) \square c_z)}{\sum_z \exp(f_{n-1}(x) \square c_z)}$$

$$\min_f - \sum_z y_z \log(\hat{y}_z)$$

*simplified for presentation

Classification

[Movshovitz-Attias et al., 2017, Zhai and Wu, 2018, Lee et al., 2020]



$$D(f_{n-1}(x), C_z) = f_{n-1}(x) \square C_z$$

Metric space $f_{n-1}(x)$ is not in normalized space

=> poor nearest neighbor search performance

$$D(f_{n-1}(x), C_z) = f_{n-1}(x) \square C_z$$

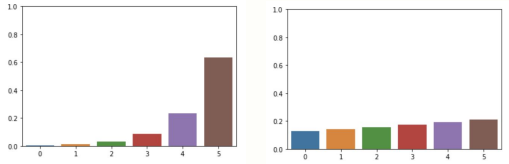
$$\hat{y}_z = \text{softmax}(D(f_{n-1}(x), C_z))$$

$$\min_f - \sum_z y_z \log(\hat{y}_z)$$

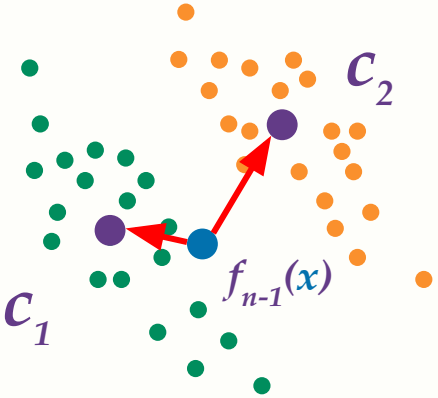
Classification in metric learning

[Movshovitz-Attias et al., 2017, Zhai and Wu, 2018, Lee et al., 2020]

Output probability $\hat{y}$



when D is in appropriate range when D is small



$$D(f_{n-1}(x), c_z) = \frac{f_{n-1}(x)}{\|f_{n-1}(x)\|} \cdot \frac{c_z}{\|c_z\|} \cdot \frac{1}{\tau}$$

or

$$D(f_{n-1}(x), c_z) = f_{n-1}(x) \cdot c_z$$

$$\hat{y}_z = \text{softmax}(D(f_{n-1}(x), c_z))$$

$$\min_f - \sum_z y_z \log(\hat{y}_z)$$

→

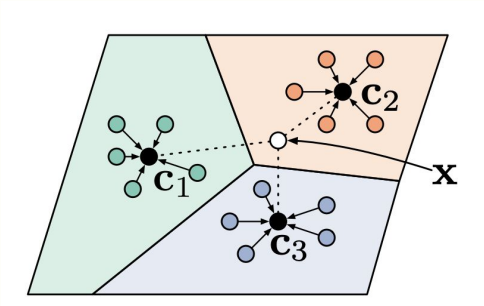
$$D(f_{n-1}(x), c_z) = \frac{f_{n-1}(x)}{\|f_{n-1}(x)\|} \cdot c_z$$

Add a normalization layer to the last hidden layer

Prototypical networks

[Snell et al., 2017]

- Prototype of a class is the mean vector of the embedding features belonging to that class
- Few-shot classification



Non-parametric prototype

$$c_z = \frac{1}{N} \sum_{i \in c_z}^{N} f(x_i)$$

$$D(f(x), c_z) = \|f(x) - c_z\|^2$$

$$\hat{y}_z = \text{softmax}(-D(f(x), c_z)) = \frac{\exp(-D(f(x), c_z))}{\sum_z \exp(-D(f(x), c_z))}$$

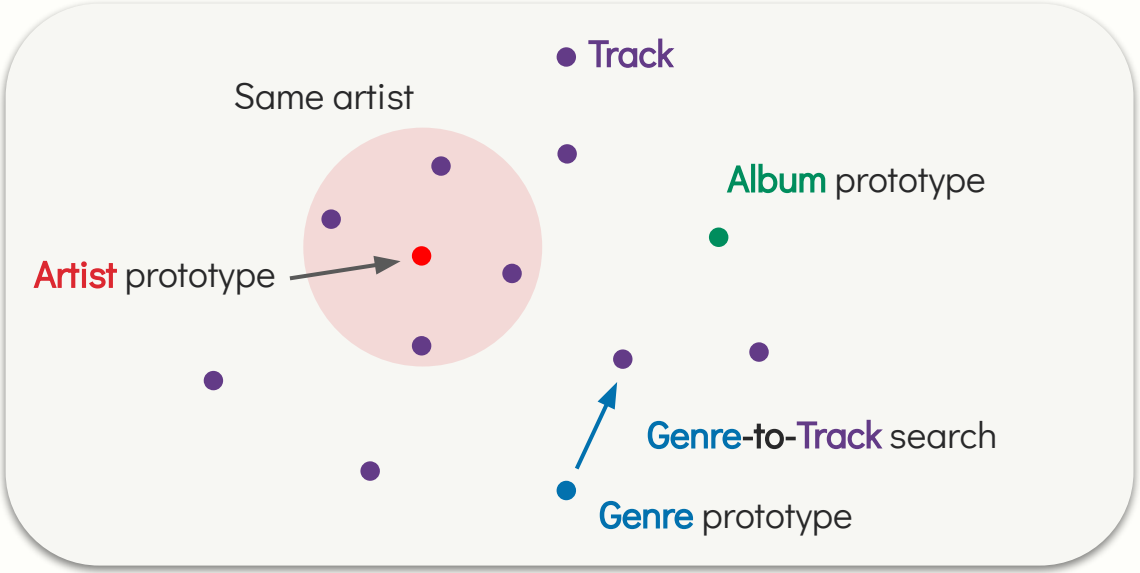
*simplified for presentation

Use of prototypes

- If we have a trained embedding function $f(\cdot)$, we can get the prototypes of the category by averaging all the embedding features belonging to the same category and use them for search

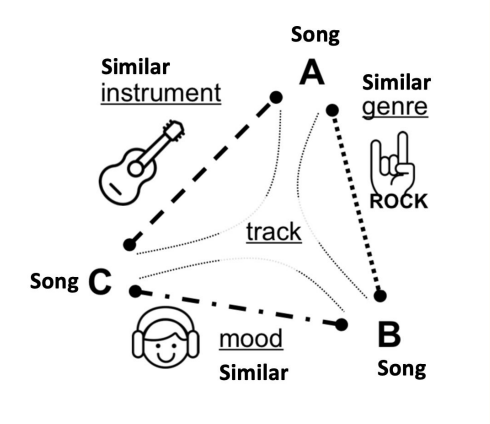
- Music items
  - Track
  - Album
  - Artist
  - Tag

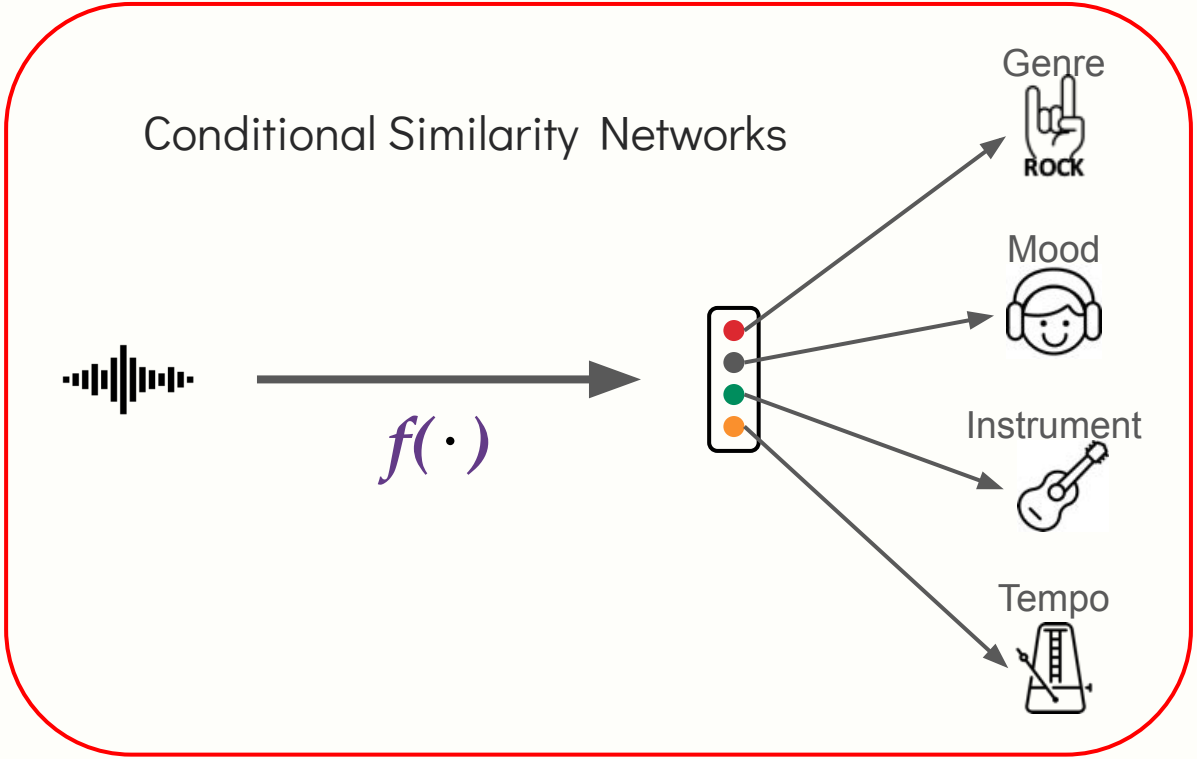
- Cross item search
  - Tag-to-Track
  - Artist-to-Track
  - Album-to-Track



Disentangled metric learning

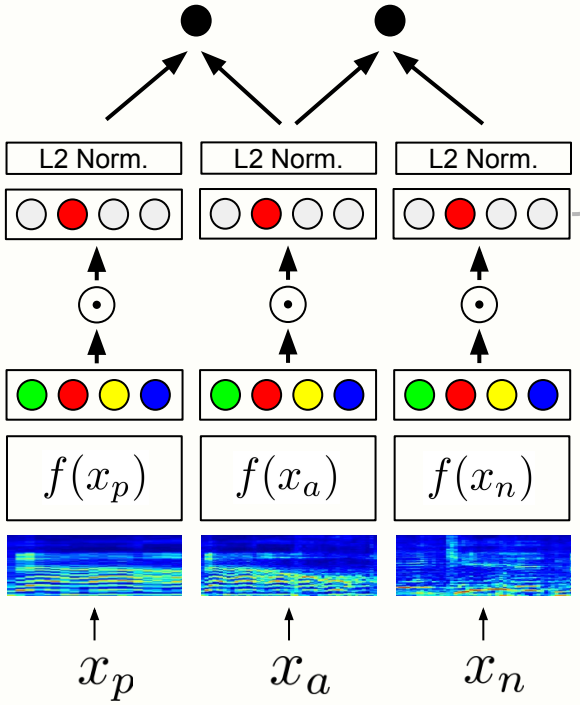
[Veit et al., 2017, Lee et al., 2020]





Disentangled metric learning

[Veit et al., 2017, Lee et al., 2020]



Mask the embedding features

depending on the notion of similarity s

(e.g. genre, mood, instruments, tempo)

$$D(f(x_i), f(x_j)) = \|f(x_i) - f(x_j)\|^2$$

$$(x_a, x_p, x_n; s)$$

$$D(f(x_i), f(x_j); s) = \|f(x_i) \circ m_s - f(x_j) \circ m_s\|^2$$

Unsupervised metric learning

[Dosovitskiy et al., 2014, Wu et al., 2018]

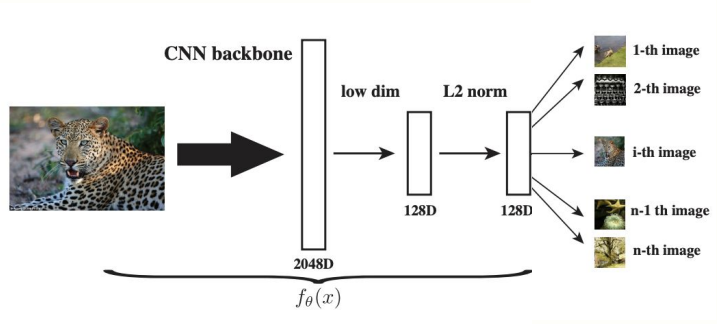
What if there are too many training instances? (e.g. millions of training instances)

- Instead of training the model using category labels, you can train the model to discriminate between instances
- Classification: augmented instance $x_i \rightarrow \tilde{x}_i$ and centroid of instances C_i

$$D(f(\tilde{x}_i), C_i) = f(\tilde{x}_i) \square C_i$$

$$\hat{y}_i = \text{softmax}(D(f(\tilde{x}_i), C_i)) = \frac{\exp(D(f(\tilde{x}_i), C_i))}{\sum_i \exp(D(f(\tilde{x}_i), C_i))}$$

$$\min_f - \sum_i y_i \log(\hat{y}_i)$$



*simplified for presentation

Unsupervised metric learning

[Chen et al., 2020]

- Instead of using centroid of instances, you can directly compare instances within batch sampling

- Metric learning: Augmented instance $x_i \rightarrow \tilde{x}_i$ and augmented instance $x_j \rightarrow \tilde{x}_j$

$$D(f(\tilde{x}_i), f(\tilde{x}_j)) = cos(f(\tilde{x}_i), f(\tilde{x}_j))$$

$$\hat{y}_{i,j} = \frac{\exp(D(f(\tilde{x}_i), f(\tilde{x}_j)) \ / \tau)}{\sum_k 1_{[k \neq i]} \exp(D(f(\tilde{x}_i), f(\tilde{x}_k)) \ / \tau)}$$

$$\min_f - \sum_{i,j} y_{i,j} \log(\hat{y}_{i,j})$$

- Track
- Album
- Artist

*simplified for presentation

Applications in MIR

- Similarity pairs or triplets [Lu et al., 2017]
  - (x_i, x_j, x_k)
- Semantic labels (tag, genre) [Schindler and Knees, 2019, Lee et al., 2020]
  - **Mostly Multi-labeled**
  - $(x, y) => (x_i, x_j, x_k)$

    Latent space similarity or whether to share the same tag
- Objective metadata (artist, album, track) [Park et al., 2018, Royo-Letelier et al., 2018, Lee et al., 2019]
  - **Free annotations**
  - **The number of classes is very large**

Semantic labels

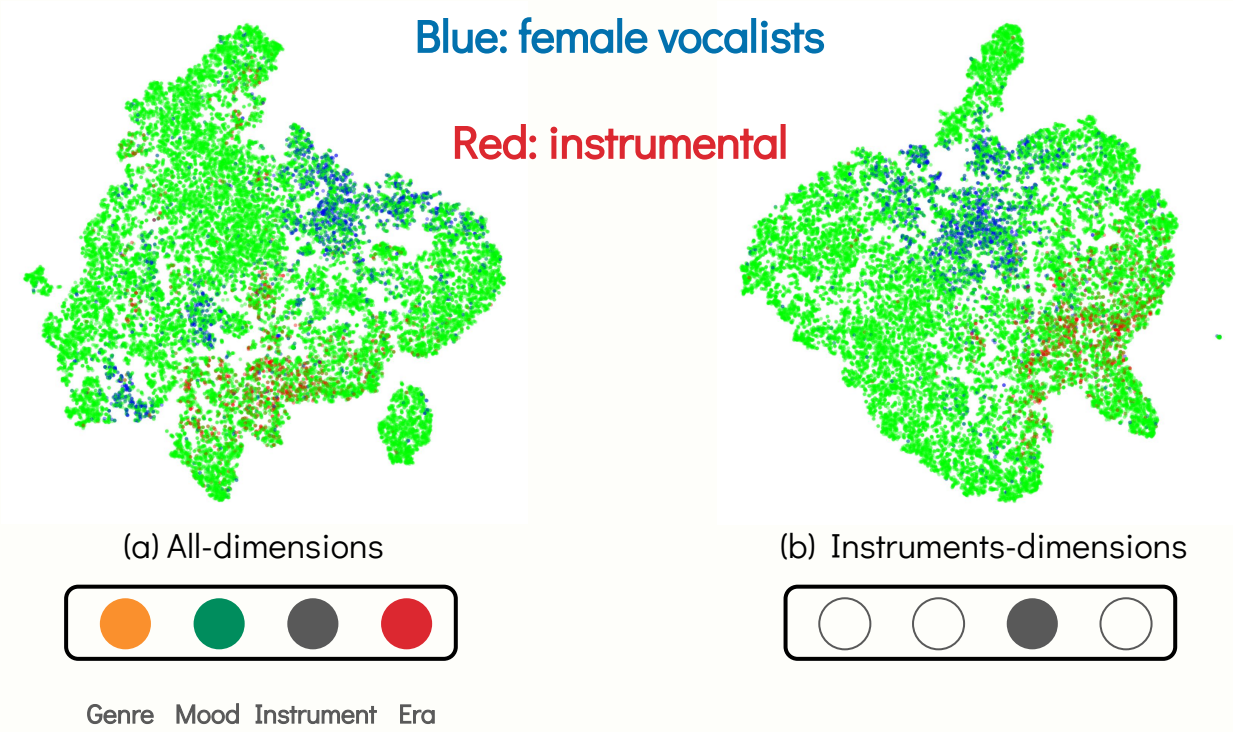
[Lee et al., 2020]

	Normalization	Similarity-based retrieval				Auto-tagging AUC
		R@1	R@2	R@4	R@8	
Triplet	yes	31.8	45.2	59.9	73.0	0.815
Classification	no	6.1	11.5	21.1	35.9	0.887
Classification	yes	43.8	57.8	70.3	80.3	0.887

- Triplet networks versus classification model using tag labels
- Evaluated in both classification (auto-tagging) and similarity-based retrieval
- For tagging evaluation of triplet networks, they measure the distance between the example and the class centroids and use them as class predictions
- The results show that
  - Triplet networks perform better in similarity-based retrieval than classification model without a normalization layer
  - However, classification model shows better performance on auto-tagging
  - **Adding a normalization layer makes the classification model performs well on both tasks**

Disentangled metric learning

[Lee et al., 2020]



Objective metadata

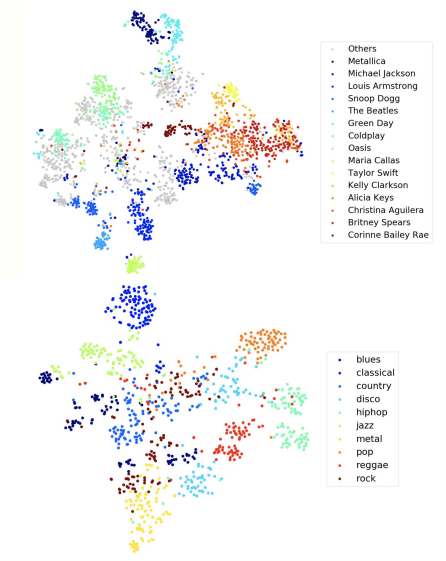
[Park et al., 2018]

	Tag-label (classification)	Artist-label (classification)	Artist-label (triplet)
GTZAN (fault-filtered)	0.6759	0.6655	0.6966
FMA small	0.5332	0.5269	0.5732

- Triplet networks versus classification model using artist labels
- Also, they are compared with classification model using tag labels
- The models are evaluated with a k-nearest neighbor genre classification based on embedding feature similarity to the held-out dataset
- The results show that
  - Artist-label classification model almost matches the performance of tag-label classification model
  - **Artist label triplet model outperforms the two classification models**

Clustering and prototype search

[Park et al., 2018]



Artist prototype nearest neighbor search

Coding time!

Summary of part 2

- We've extended linear metric learning to **deep metric learning**
- We've also introduced some advanced models and basic applications in MIR.
- In part 3, we'll see how the deep metric learning concepts can be extended to use **diverse music modalities** (e.g. audio, image, MIDI or text)!

Tutorial outline

- Part 1: Foundations (Brian McFee)
  - Linear metric learning methods
  - Overview of applications in MIR
  - Coding practice

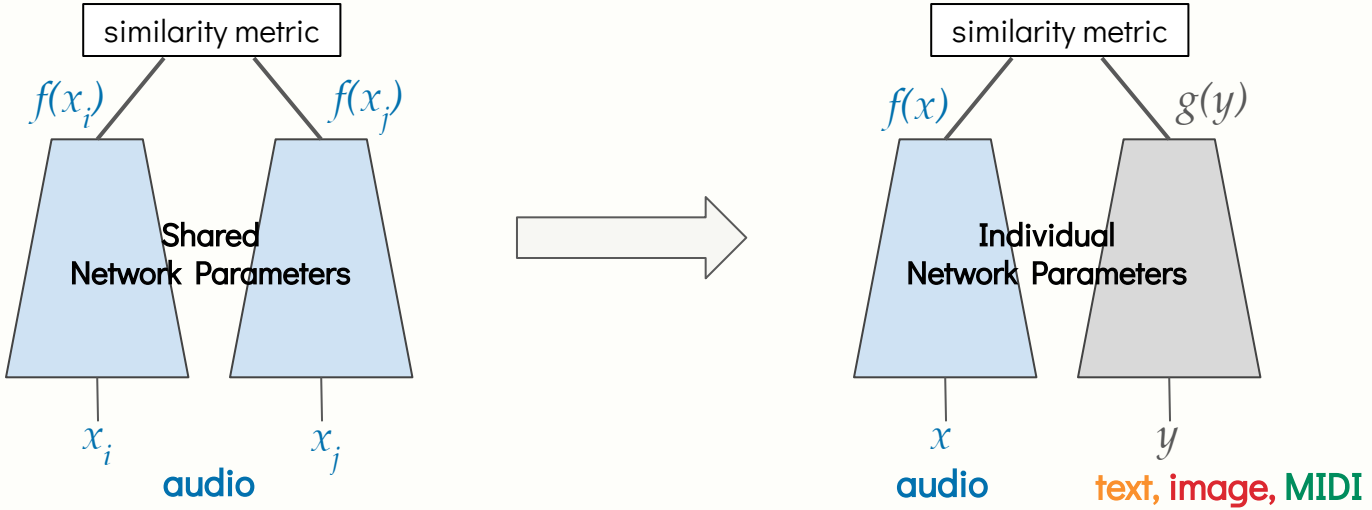
- Part 2: Deep metric learning (Jongpil Lee)
  - Linear metric learning to deep metric learning
  - Advanced models
  - Coding practice

- **Part 3: Variations and modern applications (Juhan Nam)**
  - Cross-modality metric learning
  - Unsupervised learning

- Closing remarks

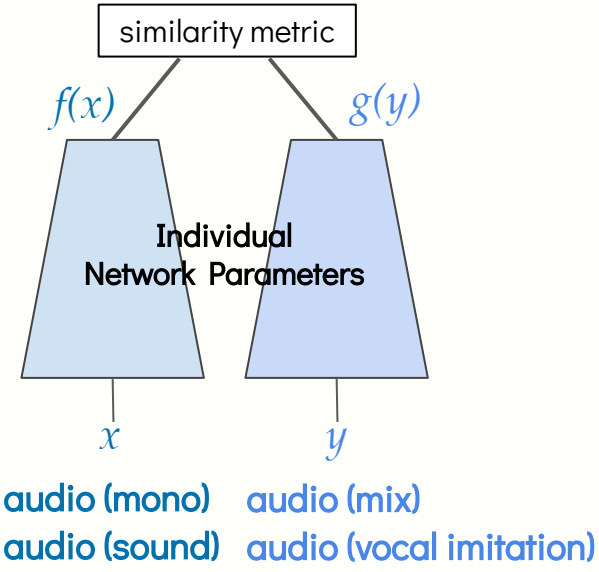
Cross-modality metric learning

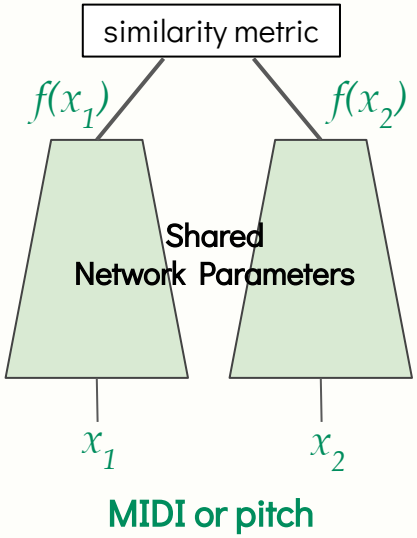
- Learning correspondence between two different modalities of inputs
  - Each modality has its own subnetwork



Cross-modality metric learning

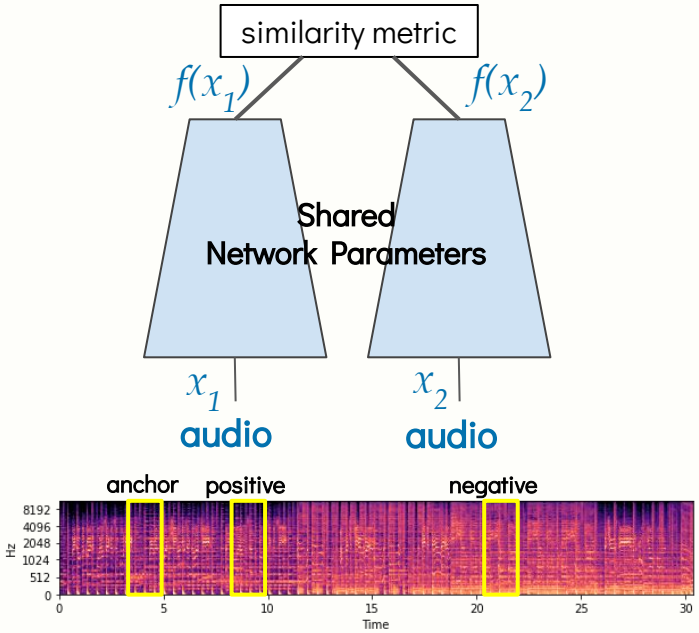
- More variations are possible
  - Different domains of audio or metric learning on symbolic data

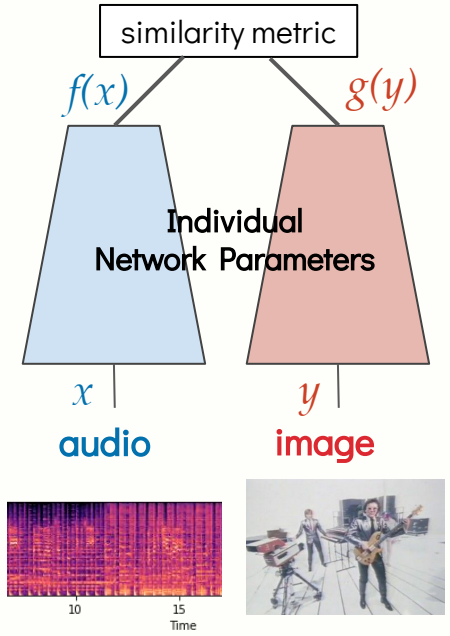




Unsupervised (or self-supervised) learning

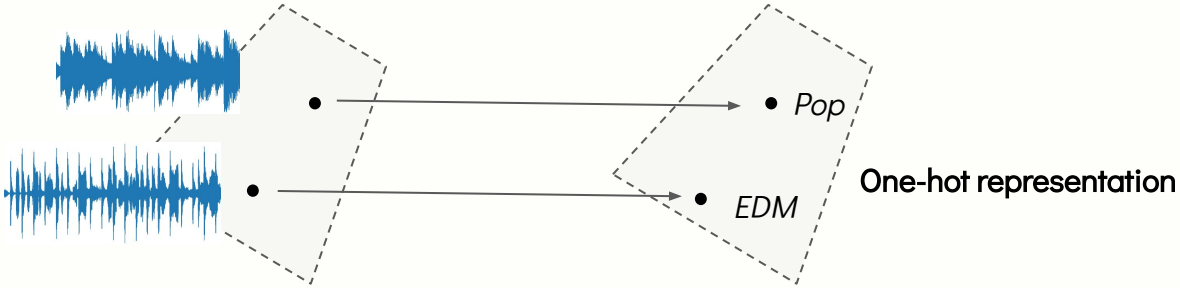
- Using **temporal proximity** in audio/music or **audio-visual correspence** in video
  - No need of manual labeling or matching





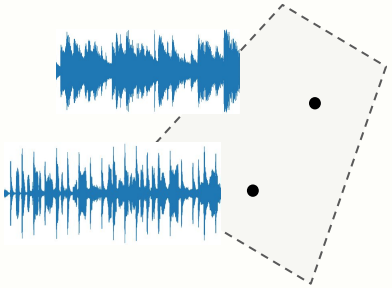
Audio and word

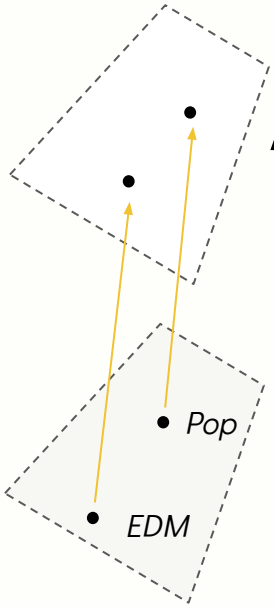
- Conventional supervised learning



Audio and word

- Learning semantic information of labels from other data sources
  - For example, regards musical instrument annotations as genre attributes: “side information”
  - Project the one-hot representation to the musical instrument embedding (attribute embedding)





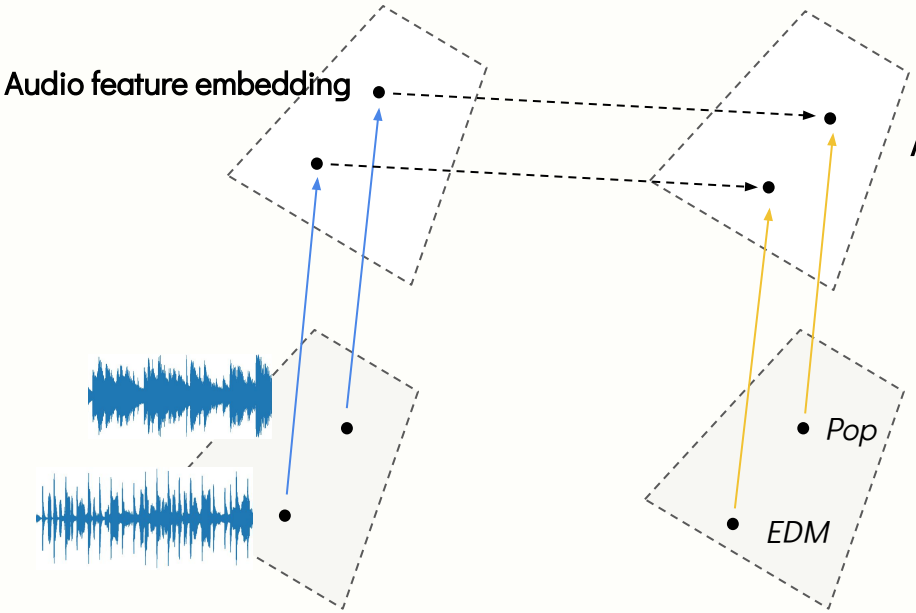
Attribute embedding

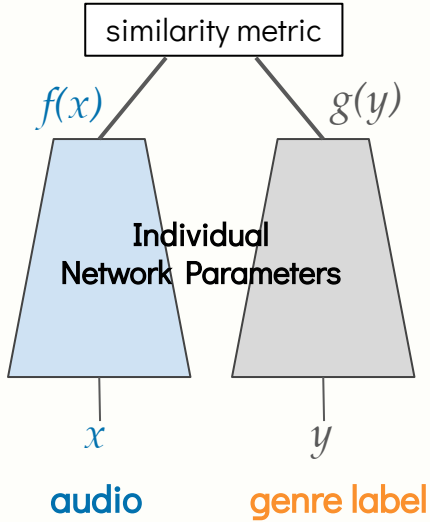
Side information: musical instrument appearances in each genre

	Drum	Bass	Guitar	Vocal	Elec drum	Synth
Pop	0.9	0.9	0.7	0.9	0.1	0.5
EDM	0.1	0.8	0.1	0.1	0.8	0.9

Audio and word

- Associates audio feature space with the attribute space using metric learning



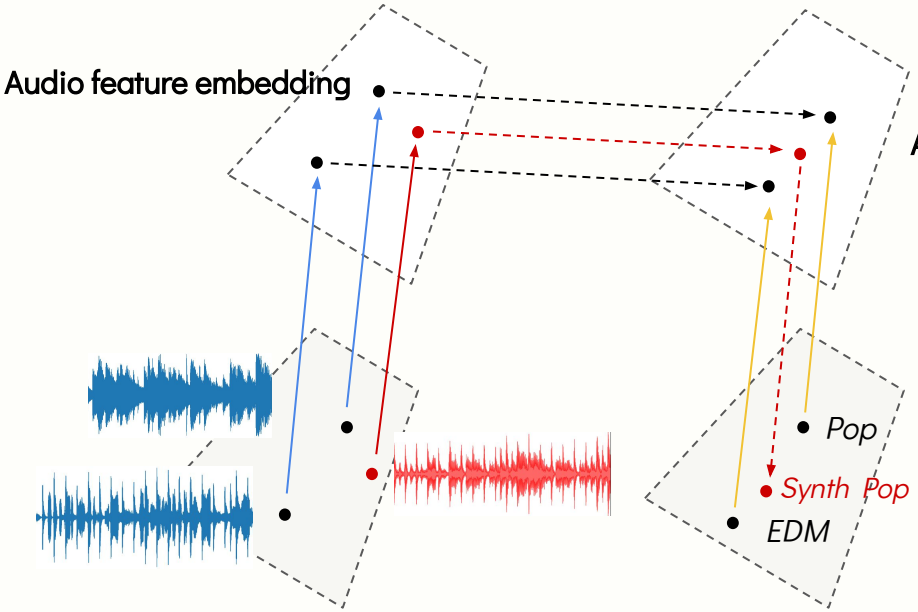


Side information: musical instrument appearances in each genre

	Drum	Bass	Guitar	Vocal	Elec drum	Synth
Pop	0.9	0.9	0.7	0.9	0.1	0.5
EDM	0.1	0.8	0.1	0.1	0.8	0.9

Audio and word: zero-shot learning

- Collect more side information than those in the training data
- This enables the model to predict unseen labels

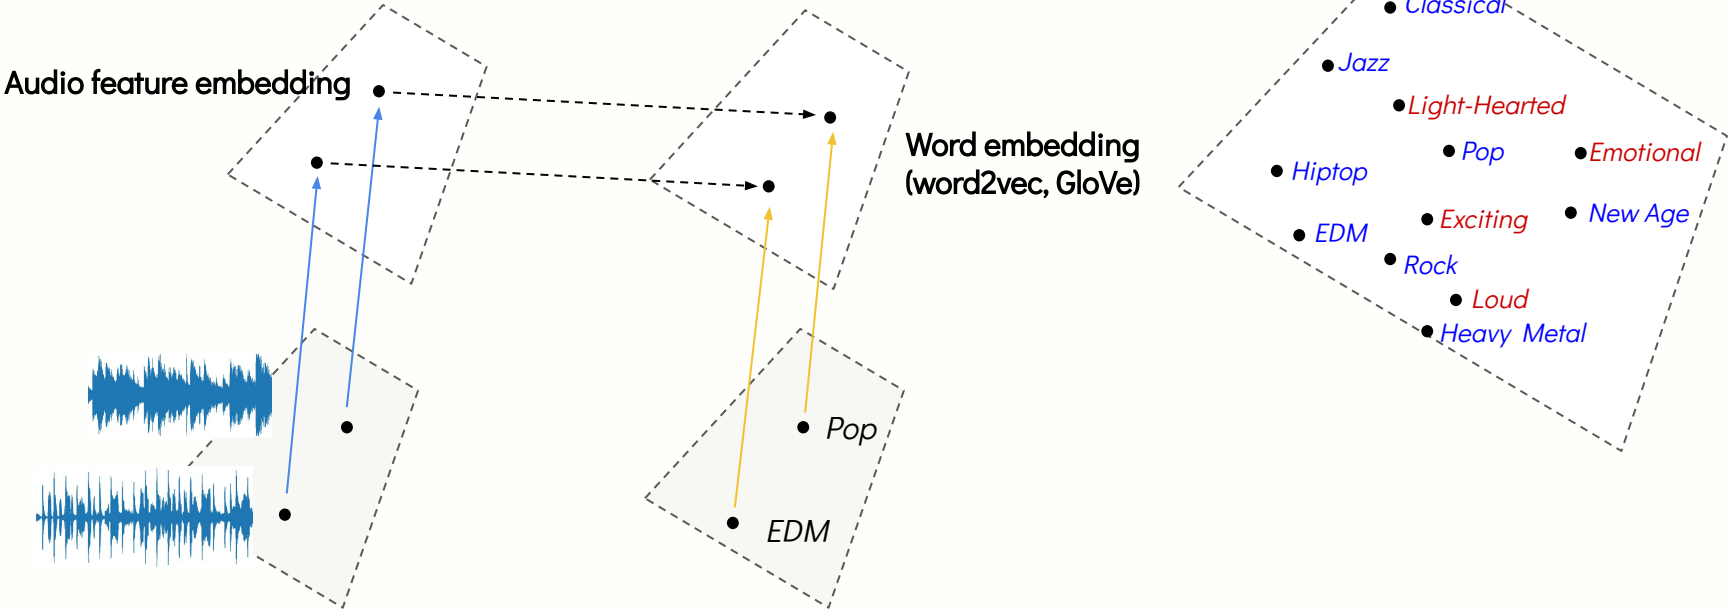


Side information: musical instrument appearances in each genre

	Drum	Bass	Guitar	Vocal	Elec drum	Synth
Pop	0.9	0.9	0.7	0.9	0.1	0.5
EDM	0.1	0.8	0.1	0.1	0.8	0.9
Synth Pop	**0.2**	**0.9**	**0.2**	**0.9**	**0.8**	**0.9**
Folk	0.5	0.3	0.9	0.9	0.0	0.1

Audio and word: zero-shot learning

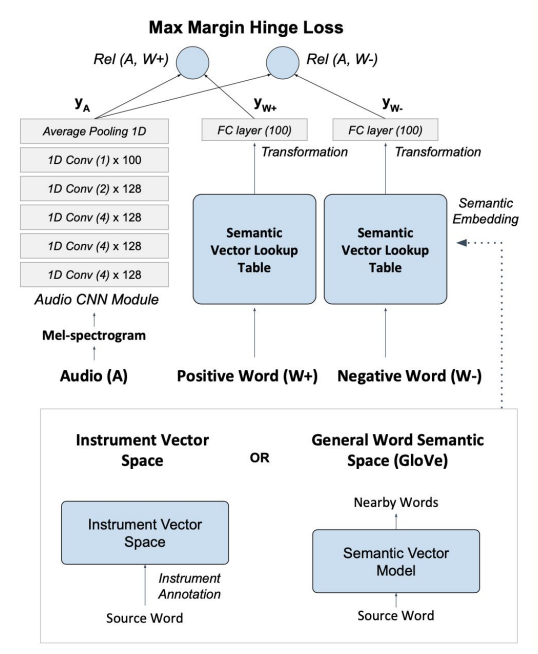
- We can also use a pre-trained word embedding
  - More rich annotations beyond music genres can be predicted!

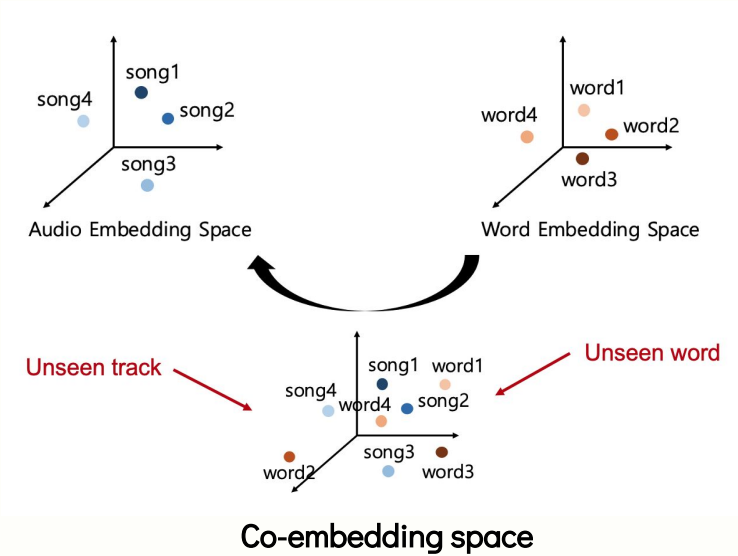


Audio and word: zero-shot learning

[Choi et al. 2019]

- Learning co-embedding between **audio** and **tags** using a triplet loss





Audio and word: zero-shot learning

[Choi et al. 2019]

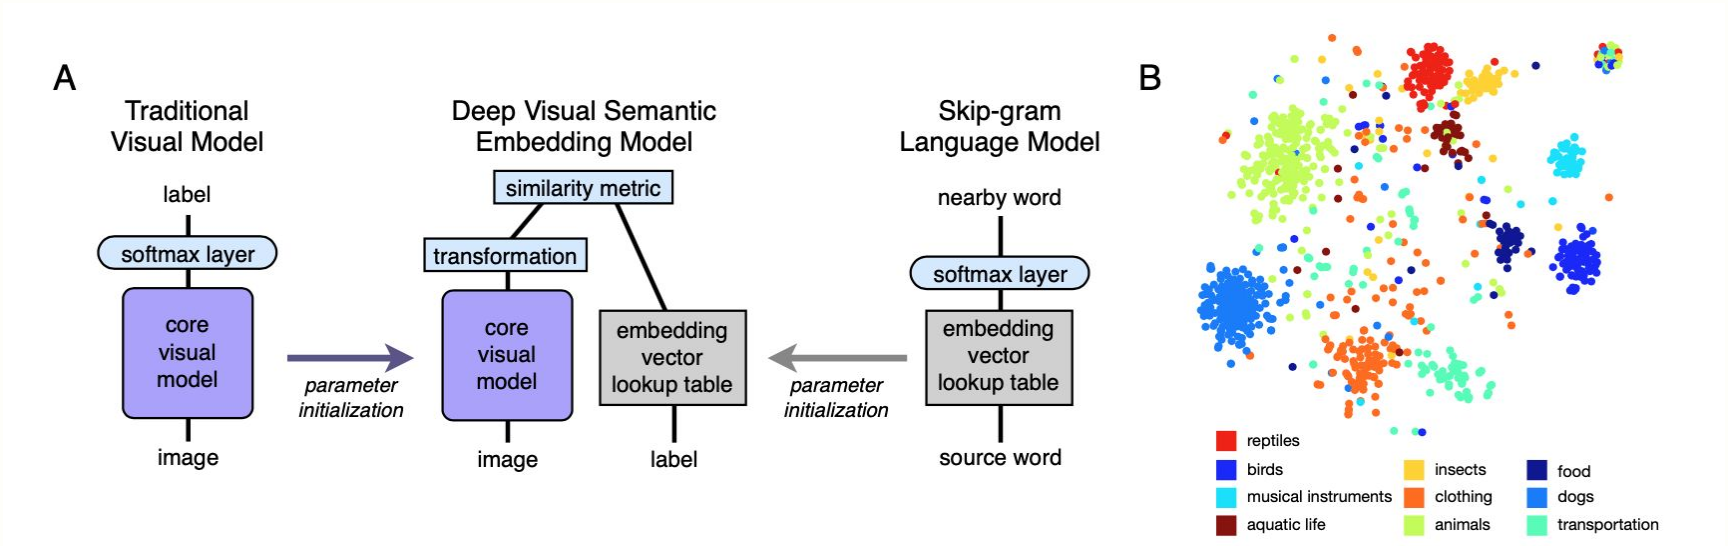
Top 5 retrieved tracks for a query word from unseen tag subset ('guitar') and an arbitrary word ('lovely')

DeViSE: a deep visual-semantic embedding model

[Frome et al. 2013]

- The seminal work in the computer vision community
  - Use word embedding for labels and associate it with image embedding
  - Pretrain each subnetwork individually before cross-modal metric learning when there is semantic gap between two modalities



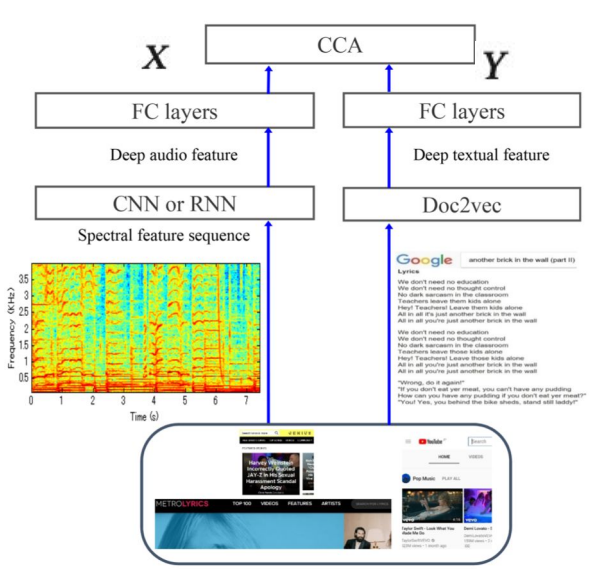
Audio and lyrics: learning the temporal correlation

[Yu et al. 2019]

- Tasks: retrieve **audio** using **lyrics** or **lyrics** using **audio**
- Summarize lyrics using “Doc2Vec”
  - Transform lyrics into a fix size of vector (300-dim) taking into account the order of words
  - 30s of audio and the corresponding lyrics are paired
- Deep Canonical Correlation Analysis (DCCA)
  - Maximize the cross-correlation between two linear projections from audio and lyrics embedding

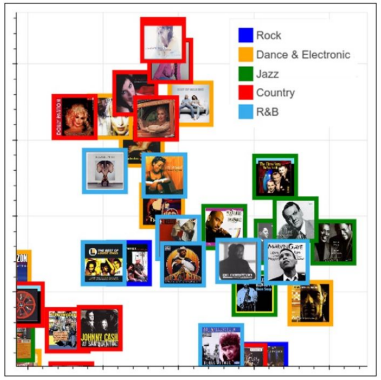
$$\underset{(H, W_X, W_Y, \varphi_x, \varphi_y)}{argmax} \; corr\left(W_X^T X, W_Y^T Y\right)$$

- RNN is more effective than CNN for audio embedding
  - Temporal order matters



Audio and album cover: genre classification

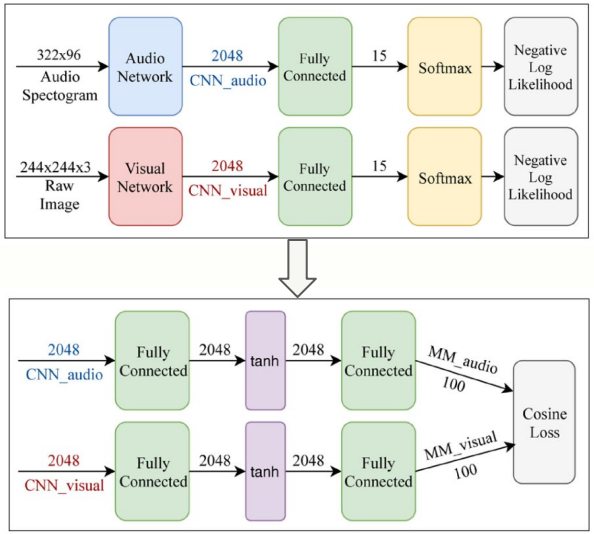
[Oramas et al. 2018]



- Learning co-embedding between **audio** and **images**
  - Audio: constant-Q transform (30s)
  - Image: album cover

- The audio and vision subnetwork are individually trained to classify genres
  - The vision subnetwork is initialized using pretrained network parameters with the ImageNet dataset

- The pretrained subnetworks are co-embedded using metric learning (triplet loss)
  - Visually or aurally-informed features are extracted for multi-label genre classification



Audio and album cover: genre classification

[Oramas et al. 2018]

- Results

Input	Model	P	R	F1
Audio	CNN_AUDIO	0.385 ± 0.006	0.341 ± 0.001	0.336 ± 0.002
	MM_AUDIO	0.406 ± 0.001	0.342 ± 0.003	0.334 ± 0.003
	CNN_AUDIO + MM_AUDIO	0.389 ± 0.005	0.350 ± 0.002	**0.346 ± 0.002**
Video	**CNN_VISUAL**	0.291 ± 0.016	0.260 ± 0.006	**0.255 ± 0.003**
	MM_VISUAL	0.264 ± 0.005	0.241 ± 0.002	0.239 ± 0.002

	ALL	0.477 ± 0.010	0.413 ± 0.002	**0.427 ± 0.000**

Visually-informed audio feature improves accuracy

Aurally-informed image feature does not help

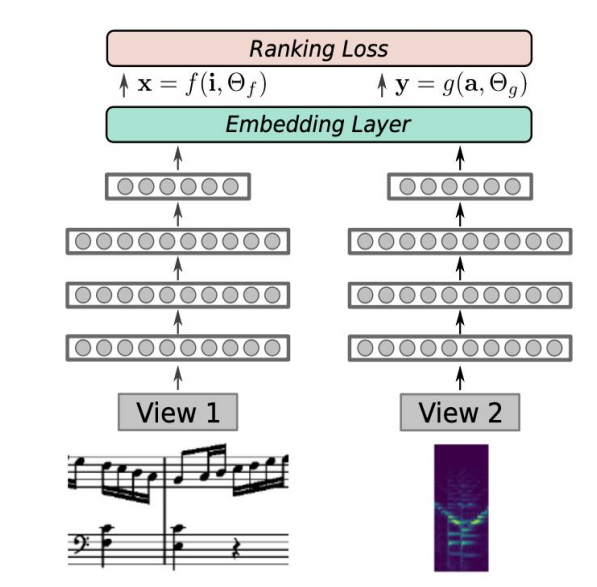
Combining all together improve accuracy further

Audio and sheet music image: short-term matching

[Dorfer et al. 2017]

- Correspond **audio** to **sheet music image**
  - Audio excerpt: 92bins x 42 frames (log-freq. spectrogram)
  - Sheet music snippet: 180 x 200 pixels
- Data augmentation
  - Audio: synthesized with different samples and tempo change
  - Sheet music: scaling, translation
- Use the triplet hinge loss
  - Cosine similarity
  - Anchor: sheet music embedding
  - Positive: matching audio
  - Negative: non-matching audio

$$\mathcal{L}_{rank} = \sum_{\mathbf{x}} \sum_{k} \max\{0, \alpha - s(\mathbf{x}, \mathbf{y}) + s(\mathbf{x}, \mathbf{y}_k)\}$$

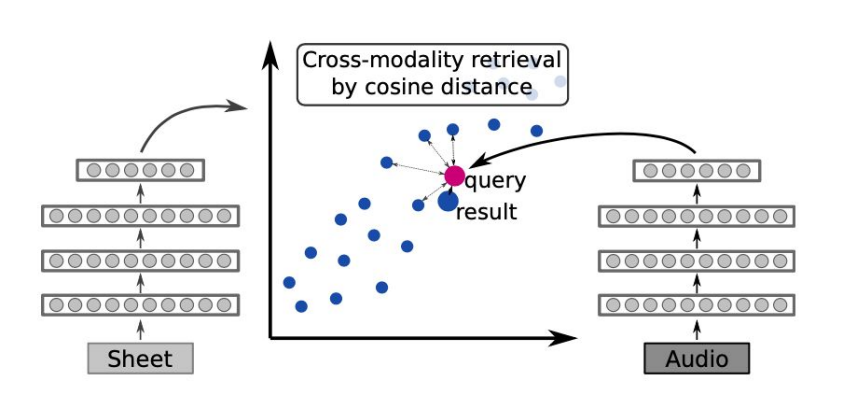


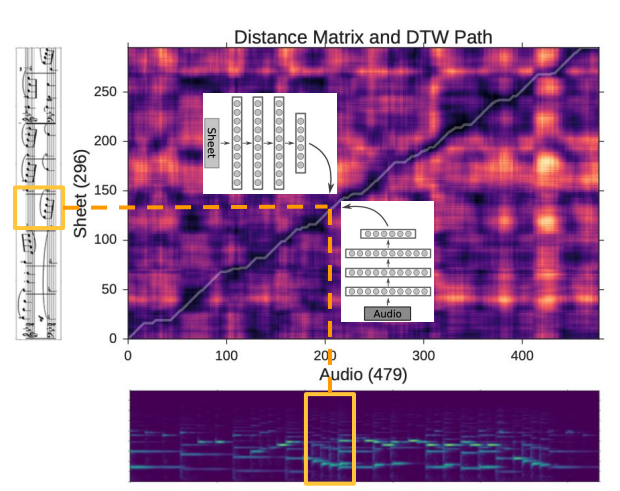
sheet music snippet audio excerpt

Audio and sheet music image: short-term matching

[Dorfer et al. 2017]

- Task 1: sheet music identification from audio queries: voting of retrieved results from all audio excerpts within a whole audio recording
- Task 2: offline alignment of a given audio with the sheet music image using the distance matrix where each point is computed from the two embeddings



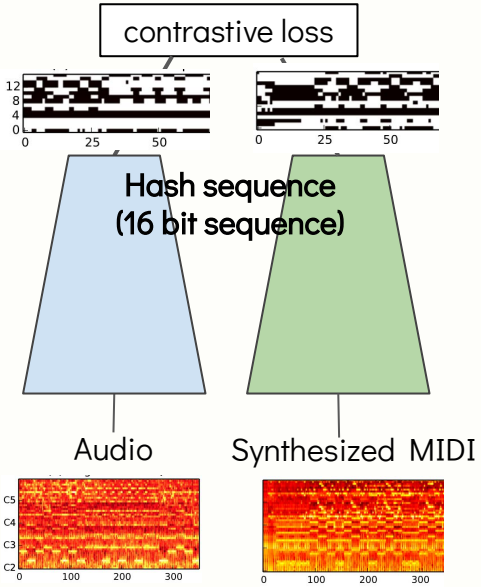


Audio and MIDI: cross-modality hashing

[Raffel and Ellis 2015]

- Large-scale content-based **MIDI**-to-**audio** retrieval
  - Find matching between 140,910 MIDI files and 994,950 audio files
  - The traditional method (DTW over CQT/chroma) is too slow!
  - Computing the distance matrix is the bottleneck

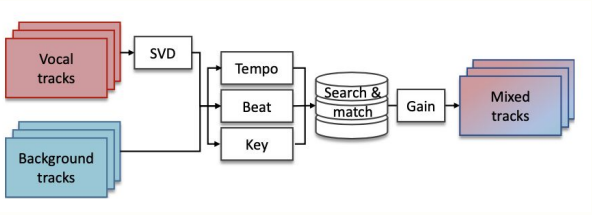
- Speed-up by learning “binary vectors” from audio and synthesized MIDI and computing hamming distance
  - Use a CNN-based Siamese network (CNN) and the contrastive loss
  - The exclusive-or operation (hamming distance) between the hash sequences is 400 times faster than the inner product between the CQT features
  - The DTW score with the hamming distance is 9 times faster



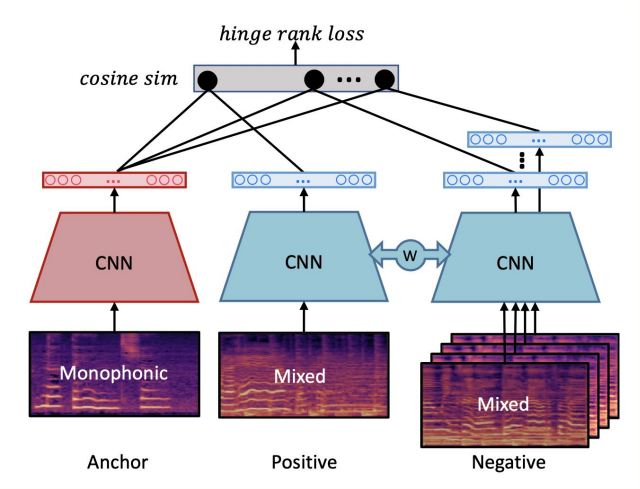
Audio-to-audio: mono and mix matching

[Lee and Nam 2019]

- Singer identification regardless of the presence of background music
- Learn co-embedding space between **monophonic audio** and its **mixed version**
- Data generation
  - Vocal track: karaoke singing (DAMP)
  - Mixed track: auto-mashup between the vocal and background tracks (musdb18) using tempo, beat, key matching



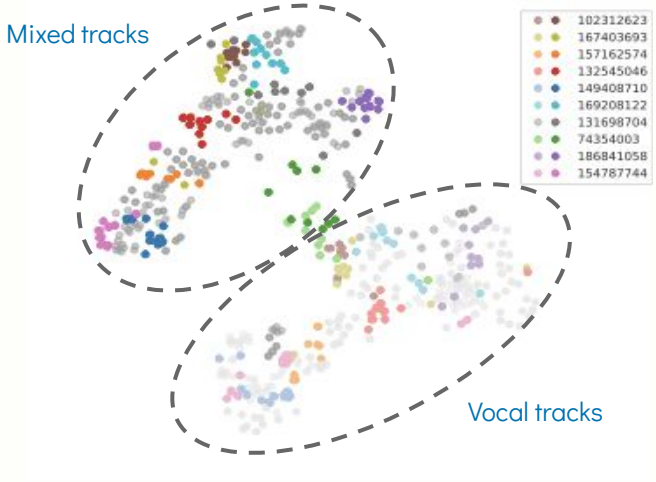
- Use the triplet hinge loss with cosine similarity



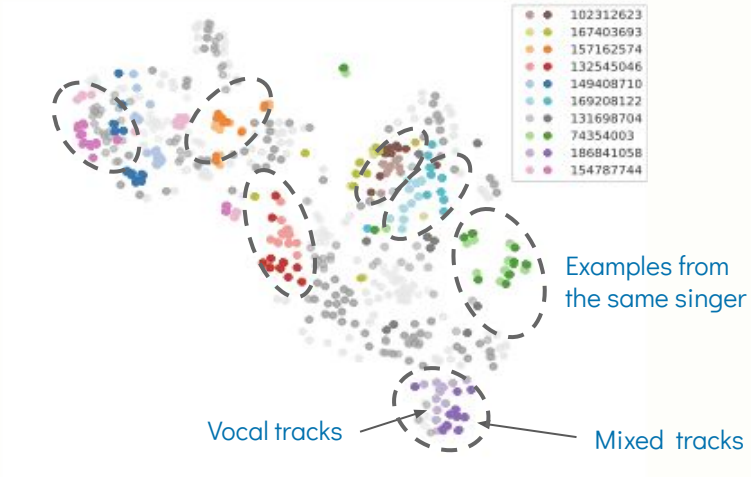
Audio-to-audio: mono and mix

[Lee and Nam 2019]

- Vocal tracks and their mixed tracks are projected closely: “implicit vocal source separation”



Before cross-modality metric learning
(the model is trained with mixed tracks only)



After cross-modality metric learning
(the model is jointly trained with mono and mixed tracks)

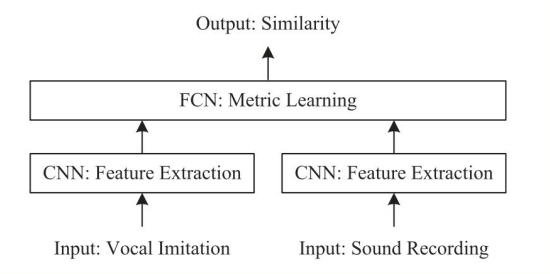
Audio-to-audio: sound sample and vocal imitation

[Zhang et al. 2019]

- Retrieve **sound samples** using **vocal imitation as query**
  - E.g.: electronic/mechanical failure sounds imitated by callers in the NPR Car Talk show

- The VocalSketch dataset
  - Crowdsourced 10 vocal imitations of a target sound
  - Everyday sounds, acoustic instrument, synthesizers

- Siamese-style network: trained to classify into paired or not paired
  - Combine the two embeddings and do the binary classification (use the categorical cross-entropy loss)



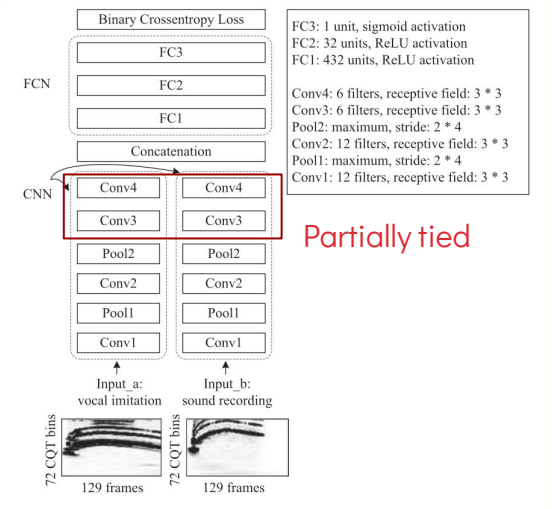
Audio-to-audio: sound sample and vocal imitation

[Zhang et al. 2019]

- Symmetric model (IMINET)
  - Two subnetworks have the same configuration
  - Network parameters (weights) are shared in different settings: tied, partially tied or untied,
  - Assuming that the two modalities share certain high-level characteristics to recognize sounds

- Results
  - Tied setting works best but the combined model is even better

Configuration	Acoustic Instr.	Comm. Synthesizers	Everyday	Single Synthesizer
Untied	0.377 ± 0.019	0.318 ± 0.020	0.154 ± 0.014	0.325 ± 0.020
Partial	0.384 ± 0.027	0.304 ± 0.015	0.154 ± 0.015	0.340 ± 0.031
Tied	0.401 ± 0.028	0.327 ± 0.019	0.158 ± 0.012	0.380 ± 0.018
Untied + Partial + Tied	**0.438 ± 0.015**	**0.343 ± 0.020**	**0.175 ± 0.012**	**0.382 ± 0.013**



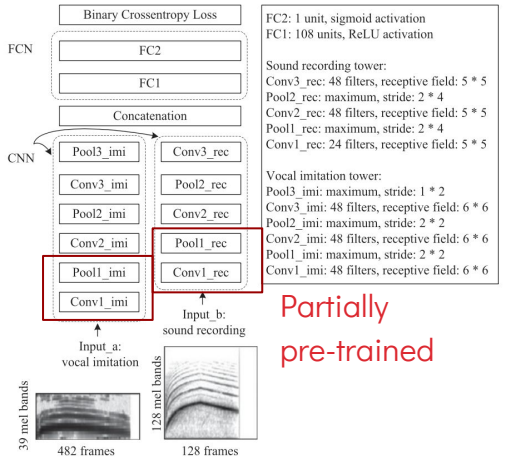
Symmetric model

Audio-to-audio: sound sample and vocal imitation

[Zhang et al. 2019]

- Asymmetric model (TL-IMINET)
  - Each subnet is trained independently
    - The vocal imitation subnetwork: to classify 7 different languages
    - The sound subnetwork: to classify 10 environmental sounds
  - The pre-trained models are transferred to the Siamese model with a different amount
    - Conv1, Conv1/2, or Conv 1/2/3
- Results
  - The fully pre-trained model (Conv 1/2/3) works best

Configuration	Acoustic Instr.	Comm. Synthesizers	Everyday	Single Synthesizer
No Pre-train	0.397 ± 0.027	0.309 ± 0.021	0.225 ± 0.023	0.377 ± 0.025
Pre-train Conv1	0.412 ± 0.033	0.328 ± 0.027	0.227 ± 0.020	0.399 ± 0.036
Pre-train Conv1/2	0.432 ± 0.024	0.325 ± 0.023	0.225 ± 0.016	**0.404 ± 0.036**
Pre-train Conv1/2/3	**0.462 ± 0.017**	**0.349 ± 0.015**	**0.246 ± 0.016**	0.390 ± 0.027



Asymmetric model

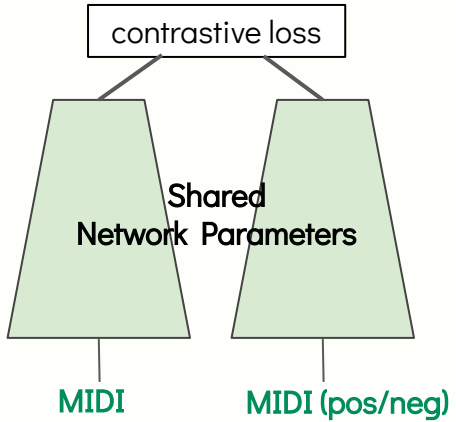
MIDI-to-MIDI: symbolic melody similarity

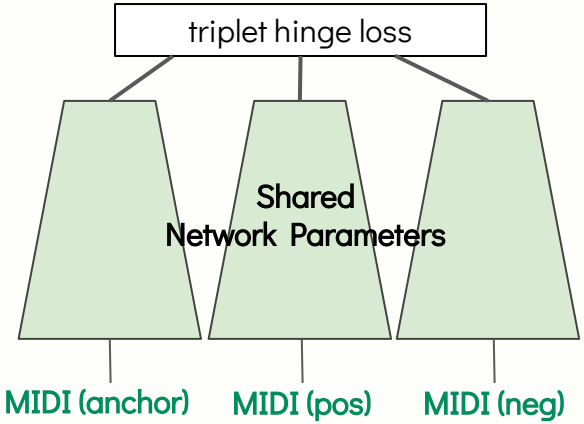
[Karsdorp et al. 2019]

- Symbolic representation learning for melody retrieval
  - MTC-FS-INST 2.0 (Meetens Tune Collection) dataset
  - 9, 336 melodies in 2,094 tune families

Three variant melodies from a tune family

- MIDI is represented as a sequence of note events
  - Each note event contains pitch, duration, beat and so on
  - Use RNN to takes the entire note event sequence as input
- Two metric learning models
  - Siamese model and triplet loss model

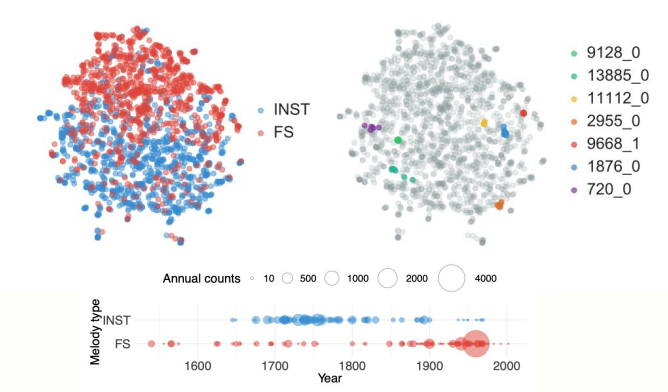




MIDI-to-MIDI: symbolic melody similarity

[Karsdorp et al. 2019]

- Visualization of the melody embedding space
  - Instrument melody and vocal melody are well-separated (They are from different years)
  - The same tune families are closely clustered



- Tune identification result
  - The Siamese model (duplet) is more effective than the triplet model
  - The RNN-based embedding is much faster than the alignment-based approach

	MAP			P@1	Sil.
	all	seen	unseen		
RNN_D	0.72	0.70	0.74	0.78	0.33
RNN_T	0.68	0.64	0.71	0.75	0.28
Alignment	0.67	–	–	0.78	0.22

Pitch-to-pitch: cover song detection

[Doras and Peeters 2019]

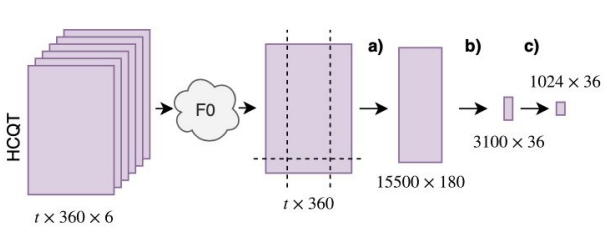


Figure 2: Input data pre-processing: dominant melody is extracted from HCQT, then a) F0 output is trimmed, b) downsampled by a factor 5 and c) resized time-wise to 1024 bins (time bins on first dimension, frequency bins on second dimension).

- Use a dominant pitch estimation model as the front-end processing
  - Summarize the pitch sequence with trimming, downsampling and resizing,
  - Represent a track with a fixed size of 1024 (time) x 36 (pitch) matrix
  - The SecondHandSongs dataset for cover song detection

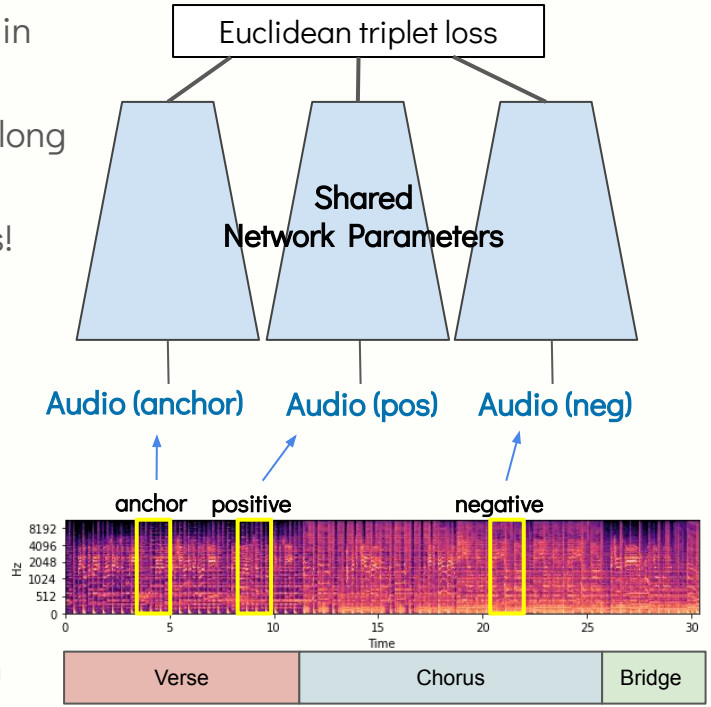
- Triplet loss model (CNN)
  - Take the track-level pitch matrix as input : no need of the alignment between two tracks
  - Online semi-hard negative pair mining
    - For each of the positive pair, if any negative pair distance is closer than the positive distance, only the negative with highest distance is kept.
    - If there is no such negative pairs, only the negative pair with lowest distance is kept.

Unsupervised learning: music segmentation

[McCallum 2019]

- Learn audio features for music segmentation
  - Exploit the time proximity of audio features that is implicit in any audio timeline.
  - Two neighboring audio segments in music are likely to belong to the same functional group such as verse or chorus
  - Possible to learn the features without segmentation labels!

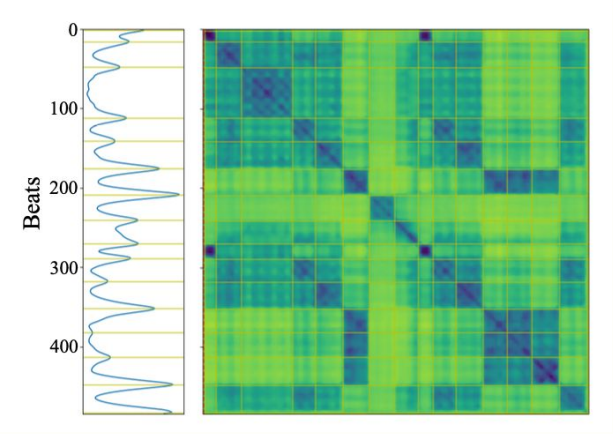
- Triplet model (CNN)
  - Audio input: beat-sync CQT
    - Input size are “snapped” on beats
    - Save the model from learning tempo-invariance
  - Biased sampling: use a signal-level distance (2D FFT log-magnitude over beat-synced CQT) between the anchor and positive to reduce false selection



Unsupervised learning: music segmentation

[McCallum 2019]

- Results
  - Beat-synchronized input improves performance
  - Biased sampling reduces false selection of positive examples



Detected boundaries (yellow) and Self-Similarity Matrix (SSM) from the learned embedding

Table 1. Performance metrics for the BeatlesTUT dataset

Algorithm	F-Measure	Precision	Recall
[4]	0.503 ± 0.18	0.579 ± 0.21	0.461 ± 0.17
[6]	0.651 ± 0.17	0.622 ± 0.19	**0.708** ± 0.19
Unsynchronized	0.597 ± 0.17	0.589 ± 0.19	0.625 ± 0.17
Beat-Synchronized	0.648 ± 0.17	0.647 ± 0.20	0.677 ± 0.18
Biased Sampling	**0.662** ± 0.17	**0.663** ± 0.20	0.691 ± 0.19

Table 2. Performance metrics for the SALAMI-A dataset

Algorithm	F-Measure	Precision	Recall
[4]	0.446 ± 0.17	0.457 ± 0.21	0.483 ± 0.19
[6]	0.493 ± 0.17	0.454 ± 0.20	0.595 ± 0.19
Unsynchronized	0.497 ± 0.16	0.429 ± 0.18	0.653 ± 0.15
Beat-Synchronized	**0.535** ± 0.15	**0.491** ± 0.20	**0.660** ± 0.16
Biased Sampling	0.533 ± 0.16	**0.491** ± 0.21	0.656 ± 0.16

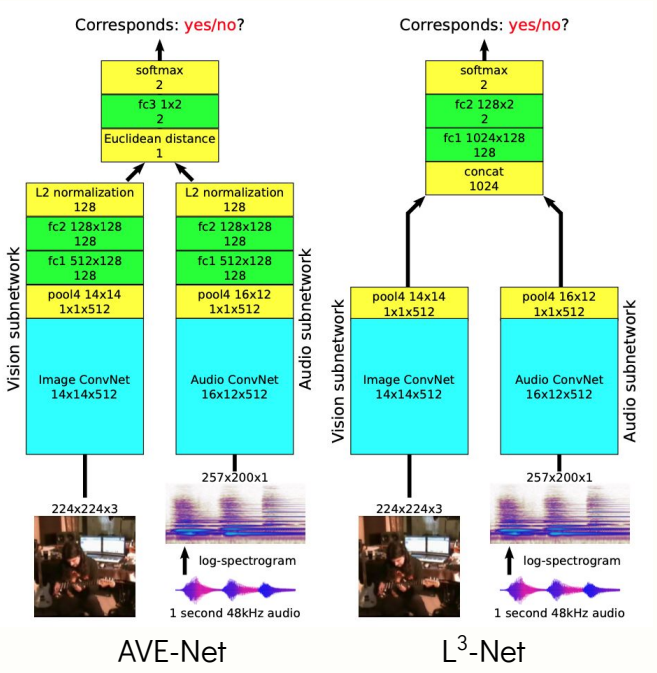
Music segmentation accuracy

Unsupervised learning: audio-visual correspondence

[Arandjelović and Zisserman, 2018]

- Use unlabeled video data
  - Given an input pair of a video frame and 1s audio, the model is trained to decide if it is from the same position
  - It is called **"self-supervision"** because the labels are constructed directly from the data itself
  - Virtually unlimited paired data!

- The audio and image embeddings are combined and classified into paired or not
  - L^3-Net (Look, Listen and Learn): concatenation
  - AVE-Net: Euclidean distance
  - AudioSet: a large collection of YouTube video clips (10s)
  - The entire networks were trained from scratch

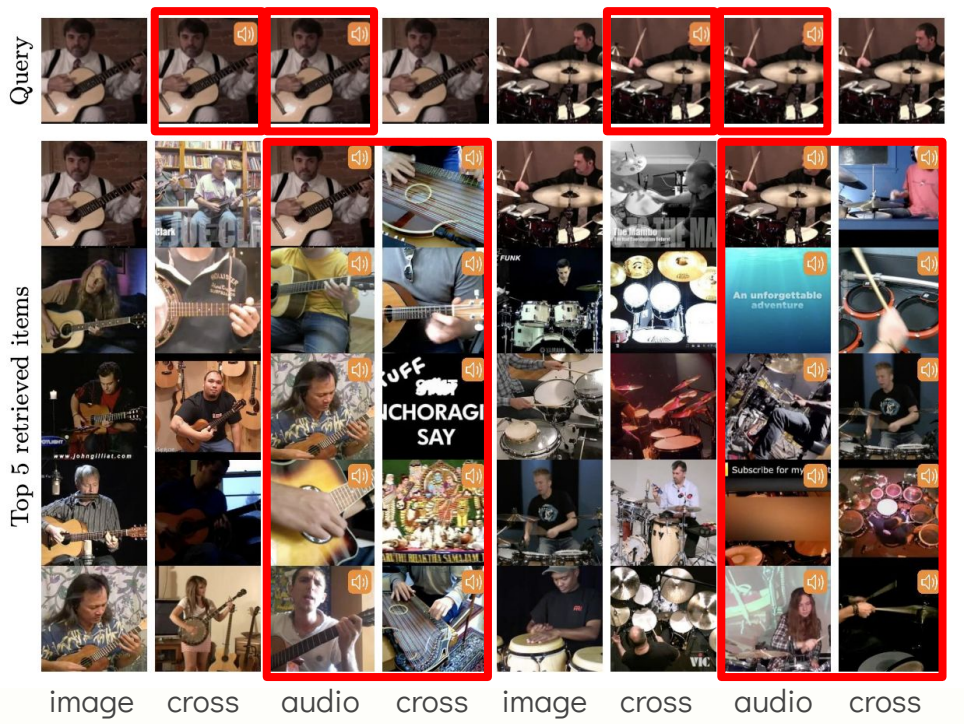


Unsupervised learning: audio-visual correspondence

[Arandjelović and Zisserman, 2018]

- Cross-modal (audio-image) and intra-modal (audio-audio, image-image) retrieval

audio only



Summary of part 3

- “Music data” include various modalities in the form of audio, image, MIDI or text
- Deep learning allows modality-agnostic representation learning
- Deep metric learning provides a flexible way of matching the different modalities of music data in a supervised or unsupervised way, from which we can learn the joint embedding space
- It is often effective to pretrain each subnetwork individually, if available, using other datasets (i.e., transfer learning) before cross-modality metric learning
- There are a lot of use cases!

Closing remarks: leverage more music data correspondences!

- Playlist (tracks, title, image)
- User data (listening history) and tracks
- Movie/game/drama: scenes and background music (mood)
- Music performance videos: performers' motion and instrumental sound

Closing remarks: trends in deep learning

- Unsupervised (or self-supervised) learning
  - Free metadata (artist/album/track) [Lee et al. 2019] or free labels (audio-visual correspondence)
  - Exploit common nature or structure of music and audio: temporal proximity, category preservation of sounds in its mixture with other sources [Jansen et al. 2018]
  - Audio effects (pitch shifting [Gfeller et al. 2020]) or musical transform (key transpose, tempo changes?)

- Semi-supervised learning
  - Use unlabeled data with data augmentation in metric learning settings

- Disentanglement of embedding space
  - Multi-level conditions (e.g., genre + tempo + instrument) is possible
  - Hierarchical disentanglement and masking

Closing remarks: open problems

- Large-scale retrieval between sequential data (e.g., cover song, midi-to-audio)
- Metric learning with score-level similarity: chord progress, rhythm pattern
- Polysemy problem
- Applications to music generation: e.g., similarity distribution for generated music

Thank you!
